

Kudla Millson lift of toric cycles and restriction of Hilbert modular forms.

Romain Branchereau*

January 12, 2025

Abstract

Let V be quadratic space of even dimension and of signature (p, q) with $p \geq q > 0$. We show that the Kudla-Millson lift of *toric* cycles - attached to algebraic tori - is a cusp form that is the diagonal restriction of a Hilbert modular form of parallel weight one. We deduce a formula relating the dimension of the span of such diagonal restrictions and the dimension of the span of toric and special cycles.

1. INTRODUCTION

1.1. Intersection numbers of geodesics on modular curves. Let $Y_0(p) = \Gamma_0(p) \backslash \mathcal{H}$ be the open modular curve for some prime p . Let γ_∞ be the image in $Y_0(p)$ of the geodesic in \mathcal{H} from 0 to ∞ . It defines a relative cycle

$$\gamma_\infty \in \mathcal{X}_1(Y_0(p), \partial Y_0(p), \mathbb{Z}). \quad (1.1)$$

On the other hand, one can attach compact geodesics to a real quadratic field $\mathbb{Q}(\sqrt{D})$. Every ideal class I in the narrow class group \mathcal{C}_D^+ defines a closed and oriented geodesic γ_I in the modular curve $Y_0(p)$. After taking linear combinations and twisting by an odd character $\psi: \mathcal{C}_D^+ \rightarrow \mathbb{C}^\times$ we get a cycle

$$\gamma_\psi = \sum_{I \in \mathcal{C}_D^+} \psi(I) \gamma_I \in \mathcal{X}_1(Y_0(p)). \quad (1.2)$$

There is a natural action of the Hecke operators on these geodesics by acting on the endpoints in \mathcal{H} , which gives an element $T_n \gamma_\psi \in \mathcal{X}_1(Y_0(p))$. Moreover, we have a pairing in homology

$$\langle -, - \rangle: H_1(Y_0(p), \mathbb{Z}) \times H_1(Y_0(p), \partial Y_0(p), \mathbb{Z}) \rightarrow \mathbb{Z}. \quad (1.3)$$

If two geodesics γ_1 and γ_2 in $Y_0(p)$ intersect transversely and in a compact set then $\langle \gamma_1, \gamma_2 \rangle = \sum_{z \in \gamma_1 \cap \gamma_2} \pm 1$ is the topological intersection number, where ± 1 depends on the local orientation at the intersection point. Darmon-Pozzi-Vonk prove the following in [DPV21, Theorem. A].

Theorem (Darmon-Pozzi-Vonk). *If p splits in $\mathbb{Q}(\sqrt{D})$, the modular form*

$$\Theta_{\gamma_\infty \otimes \gamma_\psi}(\tau) = L_p(\psi, 0) - 2 \sum_{n=1}^{\infty} \langle \gamma_\infty, T_n \gamma_\psi \rangle q^n \quad (1.4)$$

of weight 2 and level $\Gamma_0(p)$ is the diagonal restriction of a p -stabilized Hilbert-Eisenstein series $E^{(p)}(\psi, \tau, \tau)$ for a subgroup $\mathrm{SL}_2(\mathbb{Q}(\sqrt{D}))$.

In [Bra23a], we showed how to recover (and generalize) the theorem of Darmon-Pozzi-Vonk by using the Kudla-Millson lift. The idea was to consider the embedding $F^\times \subset \mathrm{SO}(d, d)$ of a totally real field F of degree d , which gives a non-compact cycle on the locally symmetric space of $\mathrm{SO}(d, d)$. The (regularized) integral of the Kudla-Millson theta lift over this cycle gives a generating series of intersection numbers generalizing the right handside of (1.4). On the other hand, the relation to a Hilbert-Eisenstein series follows from a Siegel-Weil formula and the seesaw

$$\begin{array}{ccc} \mathrm{SO}(d, d) & & \mathrm{SL}_2(F) \\ | & \searrow & | \\ F^\times & & \mathrm{SL}_2(\mathbb{Q}). \end{array}$$

In the case where F is a real quadratic field, this yields the theorem of Darmon-Pozzi-Vonk above.

Remark 1.1. Another closely related seesaw appears in [BCG20]

$$\begin{array}{ccc} \mathrm{GL}_d(\mathbb{Q}) & & \mathrm{GL}_2(F) \\ | & \searrow & | \\ F^\times & & \mathrm{GL}_2(\mathbb{Q}), \end{array}$$

where the right hand side is the diagonal restriction of (the same) Hilbert-Eisenstein series, and the left hand side is the evaluation of an Eisenstein class on the same cycle as above. The two seesaws are related by an embedding $\mathrm{GL}_d(\mathbb{Q})$ in $\mathrm{SO}(d, d)$, and the Bergeron-Charollois-Garcia lift is closely related to the Kudla-Millson lift via the Mathai-Quillen form. We hope to explain this in more detail in future work.

1.2. Main result. In this paper, we replace the torus $F^\times \subset \mathrm{SO}(d, d)$ by a more general anisotropic maximal \mathbb{Q} -torus, of maximal \mathbb{R} -rank in an orthogonal group $\mathrm{SO}(p, q)$ of signature (p, q) with $p \geq q > 0$. We restrict ourselves to anisotropic tori, to avoid having to deal with the regularization of the integral as in [Bra23a]. However, one can combine the result presented here with the result of *loc. cit.* to consider any maximal \mathbb{Q} -torus of maximal \mathbb{R} -rank, not necessarily anisotropic.

Remark 1.2. The study of cycles attached to algebraic tori in orthogonal groups is also motivated by the recent work of Darmon-Gehrmann-Linowski. In [DGL23], the authors define rigid meromorphic cocycles in arbitrary signature, generalizing the rigid meromorphic cocycles in signature $(2, 2)$ studied in [DPV21]. They conjecture that evaluated on toric cycles, these cocycles should be algebraic. The seesaws presented here could be relevant.

Let (V, Q) be a non-degenerate rational quadratic space of dimension $2d$ and signature (p, q) , where we suppose that $p \geq q > 0$. Let $\mathrm{SO}_V \subset \mathrm{GL}_{2d}$ be the orthogonal group of V and let $\mathrm{SO}_V(\mathbb{R})^+ \simeq \mathrm{SO}(p, q)^+$ be the connected component containing the identity. Let K_∞ be a maximal compact subgroup $K_\infty \simeq \mathrm{SO}(p) \times \mathrm{SO}(q) \subset \mathrm{SO}_V(\mathbb{R})^+$ and $\mathscr{D}^+ \simeq \mathrm{SO}_V(\mathbb{R})^+ / K_\infty$ its associated symmetric space, which is a pq -dimensional Riemannian manifold.

Let $\varphi_f \in \mathcal{S}(V_{\mathbb{A}_f})$ be a finite Schwartz function preserved by an open compact subgroup $K_f \subset \mathrm{SO}_V(\mathbb{A}_f)$. We set $K = K_\infty K_f$ and consider the adelic space

$$Y := \mathrm{SO}_V(\mathbb{Q}) \backslash \mathrm{SO}_V(\mathbb{A}) / K, \quad (1.5)$$

which is a finite union of locally symmetric space $\Gamma \backslash \mathscr{D}^+$ for some congruence subgroup of $\Gamma \subset \mathrm{SO}_V(\mathbb{Q})^+$.

In [KM86; KM87], Kudla and Millson construct an element

$$\Theta_\varphi^V \in H^q(Y) \otimes M_d(\Gamma'_\mathbb{Q}) \quad (1.6)$$

that realizes a lift from the homology to the space of modular forms of weight $d = \frac{p+q}{2}$ for $\Gamma'_\mathbb{Q} \subset \mathrm{SL}_2(\mathbb{Q})$ depending on the choice of the Schwartz function. As for the modular curve, there is a homological pairing

$$\langle -, - \rangle: H_q(Y, \mathbb{Z}) \times H_{pq-q}(Y, \partial Y, \mathbb{Z}) \longrightarrow \mathbb{Z}. \quad (1.7)$$

If the homology classes are represented by two smooth immersed submanifolds that intersect transversely and in a compact set, then the intersection number $\langle C_1, C_2 \rangle$ is the signed intersection number, as for geodesics. The main feature of the Kudla-Millson lift is that for a cycle C in $H_q(Y)$ it has the Fourier expansion

$$\Theta_\varphi^V(\tau, C) := \int_C \Theta_\varphi^V(\tau) = c_\varphi^0(C) + \sum_{n \in \mathbb{Q}_{>0}} \langle C, C_n(\varphi) \rangle q^n, \quad (1.8)$$

where the cycles $C_n(\varphi) \in \mathcal{X}_{pq-q}(Y, \partial Y, \mathbb{Z})$ are *special cycles* coming from embeddings $\mathrm{SO}(p-1, q) \hookrightarrow \mathrm{SO}(p, q)$.

In this paper, we will evaluate the Kudla-Millson form on cycles attached to algebraic tori. Let $T \subset \mathrm{SO}_V$ be an anisotropic algebraic \mathbb{Q} -torus, maximal and of maximal \mathbb{R} -rank. Since we assumed that $p \geq q$, the orthogonal group SO_V is of real rank q . Hence, the (maximal) real rank of T is q . Let

$$\chi = (\chi_\infty, \chi_f): T(\mathbb{Q}) \backslash T(\mathbb{A}) \longrightarrow \mathbb{C}^\times$$

be a character of finite order. The archimedean part χ_∞ is a character on $T(\mathbb{R}) \simeq (\mathbb{R}^\times)^q \times (S^1)^{\frac{p-q}{2}}$. To avoid trivial cancellations of the integral, we need to make the assumption that the character is odd, *i.e.* it is the sign function at every real place, and trivial at every complex place. Let $K_T = K_{T,\infty} K_{T,f} \subset T(\mathbb{A})$ be such that $K_{T,\infty} = K_\infty \cap T(\mathbb{R})$ is maximal compact, and that $K_{T,f} \subset K_f$. Let \mathcal{C}_T be the finite group of double cosets

$$\mathcal{C}_T := T(\mathbb{Q})^+ \backslash T(\mathbb{A}_f) / K_{T,f}. \quad (1.9)$$

We define

$$Y_T := T(\mathbb{Q}) \backslash T(\mathbb{A}) / K_T = \bigsqcup_{I \in \mathcal{C}_T} \Lambda \backslash \mathbb{R}_{>0}^q \quad (1.10)$$

where $\Lambda := T(\mathbb{Q})^+ \cap K_{T,f}$. The quotient is compact since T is anisotropic. The embedding of $T(\mathbb{A})$ in $\mathrm{SO}_V(\mathbb{A})$ induces a map $Y_T \longrightarrow Y$, and the image of the connected component $\Lambda \backslash \mathbb{R}_{>0}^q$ associated to $I \in \mathcal{C}_T$ defines a cycle $C_{T,I} \in \mathcal{X}_q(Y)$. Let us now suppose that χ_f is trivial on $K_{T,f}$. We can see the finite part χ_f as a function on $\chi_f: \mathcal{C}_T \longrightarrow \mathbb{C}^\times$ and define the cycle

$$C_\chi = \sum_{I \in \mathcal{C}_T} \chi_f(I) C_{T,I} \in \mathcal{X}_q(Y). \quad (1.11)$$

By the work of Kudla-Millson, it is known that if q is odd, then $\Theta_\varphi^V(\tau, C)$ is a cusp form for any cycle C ; see [KM90, Theorem. 2]. We show that when we restrict to the cycles C_χ , then the lift is always a cusp form.

Theorem 1.1. *Let V be an even dimensional quadratic space of signature (p, q) with $p \geq q > 0$ and let C_χ be the cycle attached to an anisotropic maximal \mathbb{Q} -torus of maximal real rank q . Then $\Theta_\varphi^V(\tau, C_\chi) \in S_d(\Gamma'_\mathbb{Q})$ is a cusp form of weight d for $\Gamma'_\mathbb{Q} \subset \mathrm{SL}_2(\mathbb{Q})$.*

In the case of toric cycles C_χ attached to isotropic \mathbb{Q} -tori, as considered in [Bra23a], the lift is not a cusp form in general. In fact, for suitable lattice in V the constant term of $\Theta_\varphi(\tau, C_\chi)$ is a partial Hecke L -function of χ .

1.2.1. The crucial fact that we want to exploit in this paper, is that any even dimensional quadratic space can be obtained by restriction of scalars of an étale algebra with involution. More precisely, let V be a quadratic space over \mathbb{Q} as before. Let $T(\mathbb{Q})$ a maximal \mathbb{Q} -torus in $\mathrm{SO}_V(\mathbb{Q})$. Then, there exists an étale algebra E of dimension $2d$ with involution ϵ and a d -dimensional subalgebra F fixed by ϵ , such that $(V, Q) \simeq \mathrm{Res}_{F/\mathbb{Q}}(E, Q_\alpha)$ where

$$Q_\alpha(x, y) = \alpha(x\epsilon(y) + \epsilon(x)y) \quad (1.12)$$

for some $\alpha \in F^\times$. Moreover, we have $T(\mathbb{Q}) \simeq E^1$ where E^1 are the elements x in E of norm $x\epsilon(x) = 1$. The quadratic extension E/F is a product of quadratic extension E_i/F_i where F_i is a field. If $E_i = F_i \times F_i$ is split, the involution permutes the two factors and $E_i^1 \simeq F_i^\times$. This is the case considered in [Bra23a]. On the other hand, when E_i/F_i is a field extension, the involution ϵ is the Galois involution $\text{Gal}(E_i/F_i)$. This is the case we want to consider in this paper. The assumption that T is \mathbb{Q} -anisotropic implies that none of the factors E_i is split. On the other hand, the assumption that the real rank of T is maximal implies that the fields F_i are totally real.

Since the torus $T(\mathbb{Q})$ is the restriction of scalars of E^1 , we obtain the following.

Theorem 1.2. *Let χ be a character on an \mathbb{Q} -anisotropic torus $T(\mathbb{Q}) \simeq E^1$ of maximal \mathbb{R} -rank. Suppose for simplicity that E is a quadratic field extension of the totally real field F of degree d . The generating series*

$$\Theta_\varphi(\tau, C_\chi) = \sum_{n \in \mathbb{Q}_{>0}} \langle C_\chi, C_n(\varphi) \rangle q^n = \Theta_\varphi(\tau, \dots, \tau, \chi) \in S_d(\Gamma'_\mathbb{Q}) \quad (1.13)$$

is the diagonal restriction of a Hilbert modular form $\Theta_\varphi(\tau_1, \dots, \tau_d, \chi)$ of parallel weight one for some subgroup of $\text{SL}_2(F)$.

If $T(\mathbb{Q}) \simeq E^1$ is an anisotropic torus attached to a product of field extensions E_i/F_i , the seesaw argument is still valid. The right-hand side becomes a sum of products of diagonally restricted Hilbert modular forms for $\text{SL}_2(F_i)$. See Theorem 3.4 for the statement.

The theorem can be summarized by the following seesaw

$$\begin{array}{ccc} \text{SO}_V(\mathbb{Q}) & & \text{SL}_2(F) \\ | & \searrow & | \\ E^1 & & \text{SL}_2(\mathbb{Q}). \end{array}$$

Remark 1.3. 1. The condition $p \geq q$ on the signature of $V_\mathbb{R}$ and on the maximality of the \mathbb{R} -rank of the torus are necessary to ensure that the cycle C_χ has dimension q and can be paired with the Kudla-Millson form of degree q .

2. This construction does not generalize to the dual pair $\text{SO}_V \times \text{Sp}_r(\mathbb{Q})$ for $r > 1$, since the tori do not give cycles of appropriate dimension. As we will see, the dimension of the cycles C_χ satisfies $\dim_\mathbb{R} C_\chi \leq q$ with equality exactly when T is maximally \mathbb{R} -split. On the other hand, when $r > 1$ the Kudla-Millson forms are not of degree q , but of degree rq . Hence, the only way the degree of the forms can match the dimension of the cycles is when $r = 1$.

1.3. Spans of diagonal restrictions and toric cycles. Let us now add the conditions that V is of dimension $p + q > 4$, where q is odd. Let $L \subset V$ be an even unimodular lattice and $\varphi_f = \mathbf{1}_{\widehat{L}}$ where $\widehat{L} = L \otimes \widehat{\mathbb{Z}}$. Let S be the set of all characters χ that are as above, odd and of finite order. Let

$$S_T := \text{span} \{ \Theta_\varphi(C_\chi) \mid \chi \in S \} \subset S_d(\text{SL}_2(\mathbb{Z})) \quad (1.14)$$

be the subspace of cusp forms spanned by the diagonal restrictions $\Theta_\varphi(C_\chi)$. Several authors (including [Li17], [BL22], [KP19] and [Yan05]) have considered spans of diagonal restrictions of Hilbert modular forms, mainly in the case of Hilbert-Eisenstein series.

On the other hand, is also natural to ask what part of the homology is spanned by cycles associated to the torus T . Let us define the subspace

$$H_T := \text{span} \{ C_\chi \mid \chi \in S \} \subset H_q(Y, \mathbb{C}) \quad (1.15)$$

spanned by the toric cycles C_χ . Let us also define

$$H_{\text{cycle}} := \text{span} \{ C_n(\varphi) \} \subset H_{pq-q}(Y, \mathbb{C}) \quad (1.16)$$

to be the span of the special cycles. The orthogonal complement is the set

$$H_{\text{cycle}}^\perp := \{ C \in H_q(Y, \mathbb{C}) \mid \langle C, C_n(\varphi) \rangle = 0 \text{ for all } n \in \mathbb{N}_{>0} \} \subset H_q(Y, \mathbb{C}). \quad (1.17)$$

With the previous conditions on the signature of V , the adjoint of the Kudla-Millson lift is injective by a result of Bruinier-Funke [BF10]. In section 5 we deduce the following.

Corollary 1.2.1. *Suppose that V is of dimension $p + q > 4$, where $p \geq q > 0$ and q odd. Then*

$$\dim(S_d(\mathrm{SL}_2(\mathbb{Z}))) - \dim(S_T) = \dim(H_q(Y, \mathbb{C})) - \dim(\mathrm{span}\{H_{\mathrm{cycle}}^\perp, H_T\}). \quad (1.18)$$

In particular, we would have $S_d(\mathrm{SL}_2(\mathbb{Z})) = S_T$ if and only if $H_q(Y, \mathbb{C}) = \mathrm{span}\{H_{\mathrm{cycle}}^\perp, H_T\}$.

Remark 1.4. Corollary 1.2.1 also holds for non-unimodular lattices, provided that the Kudla-Millson lift is injective. In particular, one could use stronger injectivity results of the Kudla-Millson lift due to Zuffetti, Metzler and Kiefer [Zuf24; MZ23; KZ23], generalizing the result of Bruinier-Funke in the unimodular case.

1.4. Examples. Let us consider some examples in signature $(2, 2)$. Let $V = \mathrm{Mat}_2(\mathbb{Q})$ be the quadratic space with the quadratic form \det . For a suitable lattice L , the locally symmetric space attached to $\mathrm{SO}(2, 2)$ is $Y_0(p) \times Y_0(p)$.

Let us first consider the étale algebra $E = \mathbb{Q}(\sqrt{D}) \times \mathbb{Q}(\sqrt{D})$ with involution being the Galois involution in both factors. After twisting by suitable characters, the toric cycle attached to $T(\mathbb{Q}) \simeq E^1$ is $\gamma_\psi \times \gamma_{\psi'}$, where γ_ψ and $\gamma_{\psi'}$ are both attached to the same real quadratic field $K = \mathbb{Q}(\sqrt{D})$, where p is split. This setting was considered by Darmon-Harris-Rotger-Venkatesh in [Dar+22], where they show that the generating series

$$\Theta_{\gamma_\psi \otimes \gamma_{\psi'}}(\tau) = \sum_{n=1}^{\infty} \langle \gamma_\psi, T_n \gamma_{\psi'} \rangle q^n \quad (1.19)$$

is the diagonal restriction of a 'Hilbert modular form' for $\mathrm{SL}_2(\mathbb{Q}) \times \mathrm{SL}_2(\mathbb{Q})$. In fact, they prove a more precise result as they express the generating series as the trace from level pD^2 to p of a product of two weight one modular forms. The corresponding seesaw is

$$\begin{array}{ccc} \mathrm{SO}(2, 2) & & \mathrm{SL}_2(\mathbb{Q}) \times \mathrm{SL}_2(\mathbb{Q}) \\ | & \searrow & | \\ \mathbb{Q}(\sqrt{D})^1 \times \mathbb{Q}(\sqrt{D})^1 & & \mathrm{SL}_2(\mathbb{Q}), \end{array}$$

where $\mathbb{Q}(\sqrt{D})^1$ are the elements of norm 1 in $\mathbb{Q}(\sqrt{D})$.

Similarly, we can consider a biquadratic field $E = \mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})$ with the involution that sends $\sqrt{D_i}$ to $-\sqrt{D_i}$. The corresponding seesaw

$$\begin{array}{ccc} \mathrm{SO}(2, 2) & & \mathrm{SL}_2(\mathbb{Q}(\sqrt{D_1 D_2})) \\ | & \searrow & | \\ \mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})^1 & & \mathrm{SL}_2(\mathbb{Q}), \end{array}$$

where $\mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})^1$ are the elements of norm 1. The image of the torus $\mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})^1$ is a product of geodesics $\gamma_1 \times \gamma_2$ where the geodesics are attached to $\mathbb{Q}(\sqrt{D_1})$ and $\mathbb{Q}(\sqrt{D_2})$ respectively. We discuss this example in Section 4.

Acknowledgments. We thank Henri Darmon for suggesting to look at these seesaws, Pierre Charollois, Luis Garcia, Håvard Damm-Johnsen and the referees for helpful comments.

2. ÉTALE ALGEBRAS WITH INVOLUTIONS AND ALGEBRAIC TORI

In this section, we review the relations between algebraic tori in orthogonal groups and étale algebras with involutions, as explained in [BCKM03], [BF14] and [DGL23].

2.0.1. Let E be a commutative \mathbb{Q} -algebra of even dimension $\dim_{\mathbb{Q}}(E) = 2d$. It is said to be *étale over \mathbb{Q}* if $E \otimes \overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}^{2d}$. Equivalently, the étale algebra E is a product of finitely many number fields R . Let ϵ be a \mathbb{Q} -linear involution on E and let $F := E^\epsilon$ be the subalgebra fixed by ϵ . We have the following three types

- i) the involution ϵ preserves each factor R and $\epsilon|_R \neq \text{id}$,
- ii) the involution ϵ does not preserve one of the factors R . In that case there is another factor R' such that $R' = \epsilon(R) \simeq R$,
- iii) the involution ϵ preserves the factor R and $\epsilon|_R = \text{id}$.

Hence we can write E as a sum $E = E_1 \times \cdots \times E_r$ of ϵ -invariant subalgebras, where $E_i = R$ is a field in case i) and iii), and $E_i = R \times R'$ is a product of fields in case ii). The fixed algebra F is then the sum $F = F_1 \times \cdots \times F_r$ where $F_i = E_i^\epsilon$ is a number field. From now on suppose furthermore that F has degree $\frac{1}{2}[E:\mathbb{Q}]$ over \mathbb{Q} . In that case we only have case i) or ii) and we deduce the following.

Proposition 2.1. *There is an element $\delta \in F^\times$ such that E is isomorphic to $F[\theta]/(\theta^2 - \delta)$ and the involution ϵ sends θ to $-\theta$.*

Proof. For the case i) the field extension E_i/F_i is of degree 2. Hence we have $E_i \simeq F_i[\theta_i]/(\theta_i^2 - \delta_i)$ for some δ_i in $F_i^\times \setminus (F_i^\times)^2$. In case ii) note we can identify $E_i \simeq F_i \times F_i$. Then we can take $\delta_i = 1$ so that we get an isomorphism

$$F_i[\theta_i]/(\theta_i^2 - 1) \longrightarrow E_i, \quad \theta_i \longmapsto (-1, 1). \quad (2.1)$$

□

2.1. Étale algebras as quadratic spaces. For α in F^\times we define a ϵ -hermitian form on E by

$$E \times E \longrightarrow E, \quad (x, y) \longmapsto \alpha x \epsilon(y). \quad (2.2)$$

It is preserved by the elements of norm 1

$$E^1 := \{x \in E^\times \mid x \epsilon(x) = 1\}. \quad (2.3)$$

Suppose that F is a field and E/F is an étale algebra. As mentioned in the introduction, the case where $E = F \times F$ is the split algebra will be excluded, hence we will restrict ourselves to the case where $E = F(\theta)$ is a quadratic field extension of F . In order to work with orthogonal groups instead of unitary groups, we view E as an F -vector space and let Q_α be the quadratic form obtained by composing the hermitian form with the trace

$$Q_\alpha: E \times E \longrightarrow F, \quad (x, y) \longmapsto \alpha \text{Tr}_{E/F} x \epsilon(y) = \alpha(x \epsilon(y) + \epsilon(x)y). \quad (2.4)$$

Let SO_E be the orthogonal group of this quadratic space. We view it as an algebraic group over F whose F -points are

$$\text{SO}_E(F) := \{g \in \text{GL}_2(F) \mid Q_\alpha(gx, gy) = Q_\alpha(x, y)\}. \quad (2.5)$$

Proposition 2.2. *Let $\delta \in F^\times$ be such that $E = F(\theta)$ with $\theta^2 = \delta$. The map*

$$E^1 \longrightarrow \text{SO}_E(F), \quad x + y\theta \longmapsto \begin{pmatrix} x & y\delta \\ y & x \end{pmatrix} \quad (2.6)$$

is a group isomorphism. Furthermore, the restriction of scalars $\text{Res}_{F/\mathbb{Q}} \text{SO}_E$ is a \mathbb{Q} -torus of rank d .

Proof. The parameter α is irrelevant here so let us assume $\alpha = 1$. With respect to the basis F -basis $\{1, \theta\}$ of E , the quadratic form Q_α has Gram matrix $\text{diag}(1, -\delta)$. It is clear that $E^1 \subset \text{SO}_E(F)$. On the other hand, for a matrix $g = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ the condition $g^T \begin{pmatrix} 1 & 0 \\ 0 & -\delta \end{pmatrix} g = \begin{pmatrix} 1 & 0 \\ 0 & -\delta \end{pmatrix}$ implies $a^2 - c^2\delta = 1$, $b^2 - d^2\delta = -\delta$ and $ab = cd\delta$. By multiplying the last equation by d on both sides and using that $ad - bc = 1$ we find that $b = c\delta$. Using the last equation again, we find that $ab = db$. If $b \neq 0$, this implies $a = d$. If $b = 0$ one can easily check that $g = \pm \mathbf{1}_2$, hence $a = d = \pm 1$.

Over $\overline{\mathbb{Q}}$, we have an isomorphism of quadratic space

$$\begin{aligned} E \otimes \overline{\mathbb{Q}} &\longrightarrow F \otimes \overline{\mathbb{Q}} \oplus F \otimes \overline{\mathbb{Q}} \\ x + \theta y &\longmapsto (x + \theta y, x - \theta y). \end{aligned} \quad (2.7)$$

On the other hand, the orthogonal group $\mathrm{SO}_E((F \otimes \overline{\mathbb{Q}})^2)$ of $(F \otimes \overline{\mathbb{Q}})^2$ is isomorphic to $(F \otimes \overline{\mathbb{Q}})^\times$, where the isomorphism is given by the map

$$\begin{aligned} (F \otimes \overline{\mathbb{Q}})^\times &\longrightarrow \mathrm{SO}((F \otimes \overline{\mathbb{Q}})^2) \\ \lambda &\longrightarrow \begin{pmatrix} \lambda & 0 \\ 0 & \lambda^{-1} \end{pmatrix}. \end{aligned} \quad (2.8)$$

Hence $(\mathrm{Res}_{F/\mathbb{Q}} \mathrm{SO}_E)(\overline{\mathbb{Q}}) \simeq (F \otimes \overline{\mathbb{Q}})^\times \simeq \overline{\mathbb{Q}}^d$, is a torus of rank d . \square

2.1.1. By restriction of scalars from F to \mathbb{Q} we obtain a $2d$ -dimensional quadratic space $(V, Q) = \mathrm{Res}_{F/\mathbb{Q}}(E, Q_\alpha)$ over \mathbb{Q} , where $V = E \simeq \mathbb{Q}^{2d}$ and the quadratic form is defined by

$$Q(x, y) := \mathrm{Tr}_{F/\mathbb{Q}} \circ Q_\alpha(x, y). \quad (2.9)$$

In particular, we have $Q(x, x) = \mathrm{Tr}_{F/\mathbb{Q}}(\alpha N_{E/F}(x))$. Moreover, by restriction of scalars we have an embedding

$$\mathrm{SO}_E(F) \hookrightarrow \mathrm{SO}_V(\mathbb{Q}). \quad (2.10)$$

By Proposition 2.2, the image of the embedding is an algebraic \mathbb{Q} -torus of rank d . Conversely, if T is a maximal \mathbb{Q} -torus in SO_V , then there is an étale algebra E such that $E^1 \simeq \mathrm{SO}_E(F) \simeq T(\mathbb{Q})$. We will recall the proof in Subsection 2.2 (see Proposition 2.4).

Remark 2.1. By abuse of notation we will occasionally also denote by Q_α the quadratic form over \mathbb{Q} , instead of Q . It should always be clear from the context if we consider the quadratic space over F or over \mathbb{Q} .

2.1.2. Let us now consider a general étale algebra E/F , with ϵ -invariant factors E_i/F_i . For any place v of \mathbb{Q} , the involution on E extends to an involution ϵ_v on $E_{\mathbb{Q}_v} := E \otimes \mathbb{Q}_v$ with fixed subalgebra $F_{\mathbb{Q}_v} := F \otimes \mathbb{Q}_v$. In the same way as before, the algebra with involution $E \otimes \mathbb{Q}_v$ is a $2d$ -dimensional quadratic space over \mathbb{Q}_v . Let w be a place of F . Let us write $F_w = (F_i)_w$ and $E_w = (E_i)_w$ for the completions at w . We set $E_v := \prod_{v|w} E_w$ and $F_v := \prod_{v|w} F_w$, which are naturally isomorphic to $E_{\mathbb{Q}_v}$ and $F_{\mathbb{Q}_v}$ respectively.

Let w be a non-archimedean place of F_i , where $E_i = F_i(\theta_i)$. Then, either $E_w = F_w(\theta_i)$ is non-split and the involution sends θ_i to $-\theta_i$, or $E_w = F_w \times F_w$ is split and the involution permutes the two factors. At a non-split place w we have

$$\mathrm{SO}_E(F_w) = \{x \in E_w^\times \mid N_{E_w/F_w}(x) = 1\}. \quad (2.11)$$

On the other hand, if w is split we have $\mathrm{SO}_E(F_w) \simeq F_w^\times$.

Define the following sets of archimedean places of F :

$$\begin{aligned} S_1 &:= \{ \text{real embeddings of } F \text{ that extend to real embeddings of } E \}, \\ S_2 &:= \{ \text{real embeddings of } F \text{ that extend to complex embeddings of } E \}, \\ S_3 &:= \{ \text{(pairs) of complex embeddings of } F \}. \end{aligned} \quad (2.12)$$

We denote the cardinality of those sets by

$$n_k := |S_k|. \quad (2.13)$$

We have $d = n_1 + n_2 + 2n_3$. For any archimedean place σ of F , the completion E_σ/F_σ is an étale algebra with involution and we have the following possibilities:

1. $F_\sigma = \mathbb{R}$ and $E_\sigma = \mathbb{R} \times \mathbb{R}$ is the split algebra where the involution ϵ permutes the two factors. In that case, we have $E_\sigma^1 \simeq \mathrm{SO}_E(F_\sigma) \simeq \mathbb{R}^\times$. This happens exactly when $\sigma \in S_1$.
2. $F_\sigma = \mathbb{R}$ and $E_\sigma = \mathbb{C}$ is the algebra where the involution ϵ is complex conjugation. In that case, we have $E_\sigma^1 \simeq \mathrm{SO}_E(F_\sigma) \simeq S^1$ where $S^1 \subset \mathbb{C}^\times$ is the unit circle. This happens when exactly when $\sigma \in S_2$.
3. $F_\sigma = \mathbb{C}$ and $E_\sigma = \mathbb{C} \times \mathbb{C}$ is the split algebra where the involution ϵ permutes the two factors. In that case, we have $E_\sigma^1 \simeq \mathrm{SO}_E(F_\sigma) \simeq \mathbb{C}^\times$. This happens for any complex place $\sigma \in S_3$ of F .

By taking the product of all archimedean places we get

$$E_\infty^1 = (\mathbb{R}^\times)^{n_1} \times (S^1)^{n_2} \times (\mathbb{C}^\times)^{n_3} = (\mathbb{R}^\times)^{n_1+n_3} \times (S^1)^{n_1+n_2}. \quad (2.14)$$

Let $E_\infty = \prod_\sigma E_\sigma$ and $F_\infty = \prod_{\sigma \in S} F_\sigma \simeq \mathbb{C}^{n_1} \times \mathbb{R}^{n_2+n_3}$. The embeddings of E give us the natural isomorphism $E_\mathbb{R} \simeq \prod_\sigma E_\sigma$ of algebras with involutions, that restricts to the natural algebra isomorphism $F_\mathbb{R} \simeq F_\infty$. Hence, we have an isomorphism of quadratic spaces $(E_\mathbb{R}, Q_\alpha) \simeq \bigoplus (E_\sigma, q_{\sigma(\alpha)})$ where $Q_{\sigma(\alpha)}(x, y) = \text{Tr}_{E_\sigma/F_\sigma}(\sigma(\alpha)x\epsilon(y))$. For $\alpha \in F^\times$ let r_α (resp. s_α) be the number of embeddings σ in S_2 such that $\sigma(\alpha)$ is positive (resp. negative). Note that $n_2 = r_\alpha + s_\alpha$.

Proposition 2.3. *The signature of $E_\mathbb{R}$ is $(n_1 + 2r_\alpha + 2n_3, n_1 + 2s_\alpha + 2n_3)$.*

Proof. We have an isomorphism of quadratic spaces $(E_\mathbb{R}, Q_\alpha) \simeq \bigoplus (E_\sigma, Q_{\sigma(\alpha)})$. We only have to find the signature at each place σ .

1. If $\sigma \in S_1$, then $E_\sigma = \mathbb{R} \times \mathbb{R}$ and the involution permutes the two factors. Hence

$$Q_{\sigma(\alpha)} \left(\begin{pmatrix} t_1 \\ t'_1 \end{pmatrix}, \begin{pmatrix} t_2 \\ t'_2 \end{pmatrix} \right) = \sigma(\alpha)(t_1 t'_2 + t'_1 t_2) \quad (2.15)$$

and E_σ has signature $(1, 1)$.

2. If $\sigma \in S_2$, then $E_\sigma = \mathbb{C} \simeq \mathbb{R}^2$ and the involution is the complex conjugation. Hence

$$Q_{\sigma(\alpha)}(z_1, z_2) = \sigma(\alpha) \text{Tr}_{\mathbb{C}/\mathbb{R}}(z_1 \bar{z}_2) = \sigma(\alpha) [\text{Re}(z_1) \text{Re}(z_2) + \text{Im}(z_1) \text{Im}(z_2)], \quad (2.16)$$

and the signature of E_σ is $(2, 0)$ if $\sigma(\alpha) > 0$ and $(0, 2)$ if $\sigma(\alpha) < 0$.

3. If $\sigma \in S_3$, then $E_\sigma = \mathbb{C} \times \mathbb{C}$ and the involution permutes the two factors. Hence

$$Q_{\sigma(\alpha)} \left(\begin{pmatrix} z_1 \\ w_1 \end{pmatrix}, \begin{pmatrix} z_2 \\ w_2 \end{pmatrix} \right) = \sigma(\alpha)(z_1 w_2 + z_2 w_1) \quad (2.17)$$

and E_σ has signature $(2, 2)$.

It follows that the signature of $E_\mathbb{R}$ is

$$n_1(1, 1) + r_\alpha(2, 0) + s_\alpha(0, 2) + n_3(2, 2) = (n_1 + 2r_\alpha + 2n_3, n_1 + 2s_\alpha + 2n_3) \quad (2.18)$$

□

2.2. Étale algebras of maximal tori. Let (V, Q) be a non-degenerate quadratic \mathbb{Q} -space of dimension $2d$ with orthogonal group SO_V . An algebraic \mathbb{Q} -group $T \subset \text{SO}_V$ is a \mathbb{Q} -torus of rank a if $T(\overline{\mathbb{Q}}) \simeq \overline{\mathbb{Q}}^a$. If K is a field extension of \mathbb{Q} , we say that T is K -split if $T(K) \simeq K^a$. A torus T is maximal if it is not contained in a torus of larger rank. The rank of a maximal K -split torus $T' \subset T$ is called the K -rank of T . The orthogonal group SO_V is of \mathbb{R} -rank q (since we assume that $p \geq q$). Hence, if T is of maximal \mathbb{R} -rank, then the \mathbb{R} -rank of T is q .

2.2.1. Consider the \mathbb{Q} -algebra $\text{End}(V)$ of \mathbb{Q} -linear endomorphism of V . We view $\text{SO}_V \subset \text{GL}_{2d}$, so that we view $\text{End}(V) \subset \text{Mat}_{2d}(\mathbb{Q})$. It is equipped with a natural involution ϵ_Q defined by

$$Q(xv, w) = Q(v, \epsilon_Q(x)w)$$

for $x \in E$. Explicitly we have $\epsilon_Q(x) = A_Q^{-1} x^T A_Q$ where A_Q denotes the Gram matrix of Q and x^T is the transpose of x . Let $E_T \subset \text{End}(V)$ be the subalgebra consisting of all the \mathbb{Q} -endomorphisms $x \in \text{End}(V)$ such that $xt = tx$ for any $t \in T(\mathbb{Q})$. We will denote it simply by E since there is no risk of confusion, and let F be the subalgebra fixed by ϵ_Q . We view $T(\mathbb{Q}) \subset \text{SO}_V(\mathbb{Q}) \subset \text{End}(V)$. The following proposition is proved in [BCKM03, Proposition. 3.3].

Proposition 2.4. *Let T be a maximal \mathbb{Q} -torus in SO_V . The algebra (E, ϵ_Q) is an étale algebra with involution. We have $2 \dim_{\mathbb{Q}} F = \dim_{\mathbb{Q}} E$.*

Proof. Over $\overline{\mathbb{Q}}$, the quadratic space V is isomorphic to $\overline{\mathbb{Q}}^{2d}$ with quadratic form $Q(v, v) = v_1 v_{d+1} + v_2 v_{d+2} + \dots + v_d v_{2d}$ i.e. with Gram matrix $\begin{pmatrix} 0 & \mathbf{1}_d \\ \mathbf{1}_d & 0 \end{pmatrix}$. With respect to this quadratic form, the torus can be diagonalized in $\mathrm{SO}_V(\overline{\mathbb{Q}})$ to

$$\mathrm{T}(\overline{\mathbb{Q}}) \simeq \{ \mathrm{diag}(t_1, \dots, t_d, t_1^{-1}, \dots, t_d^{-1}) \mid t_i \in \overline{\mathbb{Q}} \} \simeq \overline{\mathbb{Q}}^d \quad (2.19)$$

Hence, the centralizer $E \otimes \overline{\mathbb{Q}} \simeq \overline{\mathbb{Q}}^{2d}$ consists of diagonal matrices in $\mathrm{End}(V_{\overline{\mathbb{Q}}})$. Thus, E is an étale algebra. We have $\epsilon_Q(g) = g^{-1}$ for any $g \in \mathrm{SO}_V(\mathbb{Q})$. In particular, we have $\epsilon_Q(t) = t^{-1}$ for any $t \in \mathrm{T}(\mathbb{Q})$. Hence, the involution ϵ_Q preserves E since for any $x \in E$ we have

$$\epsilon_Q(x)t = \epsilon_Q(xt^{-1}) = \epsilon_Q(t^{-1}x) = t\epsilon_Q(x). \quad (2.20)$$

Moreover, the involution permutes a_i with b_i in $\mathrm{diag}(a_1, \dots, a_d, b_1, \dots, b_d) \in E \otimes \overline{\mathbb{Q}}$. It follows that

$$F \otimes \overline{\mathbb{Q}} \simeq \{ \mathrm{diag}(a_1, \dots, a_d, a_1, \dots, a_d) \mid a_i \in \overline{\mathbb{Q}} \} \simeq \overline{\mathbb{Q}}^d \quad (2.21)$$

and $2 \dim_{\mathbb{Q}} F = \dim_{\mathbb{Q}} E = 2d$. \square

2.2.2. For $\alpha \in F^\times$ we have the quadratic form

$$Q_\alpha: E \times E \longrightarrow F, \quad (x, y) \longmapsto Q_\alpha(x, y) = \alpha \mathrm{Tr}_{E/F}(x\epsilon_Q(y)) \quad (2.22)$$

that we already defined in (2.9). The restriction of scalars $\mathrm{Res}_{F/\mathbb{Q}}(E, Q_\alpha)$ is the quadratic \mathbb{Q} -vector space where the quadratic form is $\mathrm{Tr}_{F/\mathbb{Q}} \circ Q_\alpha$. Let us now prove that $\mathrm{T}(\mathbb{Q}) \simeq E^1$, where $E = E_T$ is the étale algebra with involution defined above.

Proposition 2.5. *We have $\mathrm{Res}_{F/\mathbb{Q}}(E, Q_\alpha) \simeq (V, Q)$ for some α in F^\times . Moreover, the torus $\mathrm{T}(\mathbb{Q})$ is isomorphic to $\mathrm{SO}_E(F)$.*

Proof. The algebra E acts faithfully on V . Since they have the same dimension, V is an E -module of rank 1. Let v_0 in V be a module generator, then we have an isomorphism of \mathbb{Q} vector spaces $E \simeq V$ given by $e \mapsto ev_0$. We want to check that this is an isomorphism of quadratic spaces.

The quadratic form Q induces an isomorphism of E with its dual

$$\begin{aligned} f_Q: E &\longrightarrow E^\vee = \mathrm{Hom}_{\mathbb{Q}}(E, \mathbb{Q}) \\ x &\longmapsto f_Q(x)[y] = Q(xv_0, yv_0). \end{aligned} \quad (2.23)$$

The map is E -linear in the sense that for every $e \in E$ we have $f_Q(ex) = \epsilon_Q(e)f_Q(x)$. On the other hand, the trace form also induces an E -linear isomorphism of E with its dual

$$\begin{aligned} f_{\mathrm{Tr}}: E &\longrightarrow E^\vee = \mathrm{Hom}_{\mathbb{Q}}(E, \mathbb{Q}) \\ x &\longmapsto f_{\mathrm{Tr}}(x)[y] = \mathrm{Tr}_{F/\mathbb{Q}}(x\epsilon_Q(y)). \end{aligned} \quad (2.24)$$

It is also linear in the sense that $f_{\mathrm{Tr}}(ex) = \epsilon_Q(e)f_{\mathrm{Tr}}(x)$. Hence $f_{\mathrm{Tr}}^{-1} \circ f_Q$ is an E -linear automorphism of E , satisfying $(f_{\mathrm{Tr}}^{-1} \circ f_Q)(xe) = x(f_{\mathrm{Tr}}^{-1} \circ f_Q)(e)$. It follows that $f_{\mathrm{Tr}}^{-1} \circ f_Q(x) = \alpha x$ for some nonzero α in E , so that $f_Q(x) = f_{\mathrm{Tr}}(\alpha x)$. Hence, for any x, y in E

$$Q(xv_0, yv_0) = \mathrm{Tr}_{F/\mathbb{Q}}(\alpha x\epsilon_Q(y)). \quad (2.25)$$

By the symmetry of Q , after setting $y = 1$ we have

$$\begin{aligned} 0 &= Q(xv_0, v_0) - Q(v_0, xv_0) \\ &= \mathrm{Tr}_{F/\mathbb{Q}}(\alpha x) - \mathrm{Tr}_{F/\mathbb{Q}}(\alpha \epsilon_Q(x)) \\ &= \mathrm{Tr}_{F/\mathbb{Q}}(\alpha x) - \mathrm{Tr}_{F/\mathbb{Q}}(\epsilon_Q(\alpha)x) \\ &= \mathrm{Tr}_{F/\mathbb{Q}}((\alpha - \epsilon_Q(\alpha))x) \end{aligned} \quad (2.26)$$

for any x in E . Since the trace form is non-degenerate, it follows that α is in F^\times .

Finally, let us prove that $\mathrm{T}(\mathbb{Q}) \simeq \mathrm{SO}_E(F)$. We have shown that $E^1 \simeq \mathrm{SO}_E(F)$. On the one hand, for $t \in \mathrm{T}(\mathbb{Q})$ we have $Q(tv, w) = Q(v, t^{-1}w)$. On the other hand, by definition of the involution ϵ_Q we have $Q(tv, w) = Q(v, \epsilon_Q(t)w)$. Hence $\epsilon_Q(t) = t^{-1}$ and $t \in E^1$. This shows the inclusion $\mathrm{T}(\mathbb{Q}) \subset E^1$, and the equality follows from the fact that $\mathrm{T}(\mathbb{Q})$ is a maximal \mathbb{Q} -torus contained in the (also maximal) torus E^1 , see Proposition 2.2. \square

Proposition 2.6. *If T has maximal \mathbb{R} -rank, then $n_1 = q$ and F is totally real.*

Proof. From Proposition 2.5 we have $T(\mathbb{Q}) \simeq \mathrm{SO}_E(F) \simeq E^1$. Let n_k be defined as in (2.13): n_1 is the number of real embedding of F that extend to real embeddings of E , n_2 is the number of real embeddings of F that extend to a complex embedding of E and n_3 is the number of (pairs) of complex embeddings of F . By (2.14), we have $T(\mathbb{R}) \simeq E_\infty^1 = (\mathbb{R}^\times)^{n_1+n_3} \times (S^1)^{n_1+n_2}$, hence $a = n_1 + n_3$ and $b = n_1 + n_2$. On the other hand, by Proposition 2.3, the signature of $V_\mathbb{R} = E_\mathbb{R}$ is $(p, q) = (n_1 + 2r_\alpha + 2n_3, n_1 + 2s_\alpha + 2n_3)$, where r_α (respectively s_α) is the number of places in S_2 for which $\sigma(\alpha)$ is positive (respectively negative). So if T has maximal \mathbb{R} -rank, then $a = q$ and we must have $n_3 = s_\alpha = 0$. \square

3. KUDLA-MILLSON THETA CORRESPONDENCE

3.1. Weil representation. Let $(\mathcal{V}, \mathcal{Q})$ be a quadratic space of dimension $2m$ over a totally real field \mathbb{k} of dimension k . Let $\mathrm{SO}_\mathcal{V}$ be the orthogonal group of \mathcal{V} . We will consider the following two cases:

- the field is $\mathbb{k} = \mathbb{Q}$ of degree $k = 1$ and the quadratic space $(\mathcal{V}, \mathcal{Q})$ is an arbitrary quadratic space (V, Q) like in the introduction, of dimension $2m = 2d$. The group $\mathrm{SO}_\mathcal{V}$ is the orthogonal group SO_V .
- the field $\mathbb{k} = F$ is an arbitrary totally real field of degree $k = d$. The quadratic space is $\mathcal{V} = E$, where E is an étale algebra viewed as quadratic space of dimension $2m = 2$ over F , and equipped with the quadratic form Q_α . The orthogonal group $\mathrm{SO}_\mathcal{V} = \mathrm{SO}_E \simeq E^1$ is a torus.

3.1.1. Let $\mathcal{W} = \mathcal{V} \oplus \mathcal{V} \simeq \mathcal{V} \otimes \mathbb{k}^2$ be the $4m$ -dimensional symplectic space over \mathbb{k} with the symplectic form

$$\mathcal{B} \left(\begin{pmatrix} v_1 \\ v_2 \end{pmatrix}, \begin{pmatrix} w_1 \\ w_2 \end{pmatrix} \right) = \mathcal{Q}(v_1, w_2) - \mathcal{Q}(w_1, v_2). \quad (3.1)$$

Its symplectic group is $\mathrm{Sp}(\mathcal{W}) \simeq \mathrm{Sp}_{4m}(\mathbb{k})$. At a place w of \mathbb{k} , let $\mathcal{V}_w := \mathcal{V} \otimes k_w$ be the completion. There is a local projective unitary representation ω on the space $\mathcal{S}(\mathcal{V}_w)$ of Schwartz-Bruhat functions, called the Weil representation. It is a projective representation in the sense $\omega(g_1 g_2) = c(g_1, g_2) \omega(g_1) \omega(g_2)$ for some complex cocycle $c(g_1, g_2)$ satisfying $|c(g_1, g_2)| = 1$. After passing to the adèles, we get a unitary representation

$$\omega: \mathrm{Sp}_{4m}(\mathbb{k}) \longrightarrow \mathcal{U}(\mathcal{S}(\mathcal{V}_\mathbb{A})), \quad (3.2)$$

which is again only projective. However, for certain subgroups of $\mathrm{Sp}(\mathcal{W}_\mathbb{A})$ the cocycle is trivial and we obtain a true (*i.e.* non-projective) representation. Let us consider some special cases and give some concrete formulas for the Weil representation.

3.1.2. Consider the subgroup $\mathrm{SL}_2(\mathbb{k}) \subset \mathrm{Sp}_{4m}(\mathbb{k})$, embedded as

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \longmapsto \begin{pmatrix} a & & b & & \\ & \ddots & & \ddots & \\ & & a & & b \\ c & & d & & \\ & \ddots & & \ddots & \\ & & c & & d \end{pmatrix}. \quad (3.3)$$

The subgroup $\mathrm{SO}_\mathcal{V}(\mathbb{k}) \subset \mathrm{Sp}_{4m}(\mathbb{k})$, embedded as

$$h \longmapsto \begin{pmatrix} h & 0 \\ 0 & h \end{pmatrix} \quad (3.4)$$

commutes with $\mathrm{SL}_2(\mathbb{k})$. Hence, we can embed the product $\mathrm{SL}_2(\mathbb{k}) \times \mathrm{SO}_\mathcal{V}(\mathbb{k})$ as a subgroup of $\mathrm{Sp}_{4m}(\mathbb{k})$. After passing to the adèles, the projective representation of $\mathrm{Sp}_{4m}(\mathbb{A}_\mathbb{k})$ restricts to a true

representation

$$\omega: \mathrm{SL}_2(\mathbb{A}_{\mathbb{K}}) \times \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{K}}) \longrightarrow \mathcal{S}(\mathcal{V}_{\mathbb{A}}). \quad (3.5)$$

Let us describe this action more precisely, on a Schwartz function $\varphi = \varphi_{\infty} \otimes \varphi_f \in \mathcal{S}(\mathcal{V}_{\mathbb{R}}) \otimes \mathcal{S}(\mathcal{V}_{\mathbb{A}_f})$. For $h \in \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{K}})$, we have

$$(\omega(1, h)\varphi)(v) = \varphi(h^{-1}v). \quad (3.6)$$

Suppose we can decompose the Schwartz function as $\varphi = \otimes_w \varphi_w$ where φ_w is in $\mathcal{S}(\mathcal{V}_w)$ and the product is over places of \mathbb{K} . Let us write down the local Weil representation of $\mathrm{SL}_2(\mathbb{K}_w)$ on φ_w . If $g = \begin{pmatrix} a & 0 \\ 0 & a^{-1} \end{pmatrix}$ for some $a \in \mathbb{K}_w^{\times}$, then

$$(\omega(g, 1)\varphi)(v) = |a|_w^m \varphi_w(av). \quad (3.7)$$

If $g = \begin{pmatrix} 1 & b \\ 0 & 1 \end{pmatrix}$ for some $b \in \mathbb{K}_w$, then

$$(\omega(g, 1)\varphi)(v) = \chi_w \left(\frac{b\mathcal{Q}(v, v)}{2} \right) \varphi(v). \quad (3.8)$$

Finally, if $S = \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}$, then

$$(\omega(S, 1)\varphi)(v) = \int_{\mathcal{V}_w} \varphi_w(u) \chi_w(\mathcal{Q}(v, u)) du_w. \quad (3.9)$$

Remark 3.1. The character χ_w is defined as follows. We fix the additive character e_v on \mathbb{Q}_v defined by

$$e_v(x) := \begin{cases} e^{2i\pi x} & \text{if } v = \infty \\ e^{-2i\pi \{x\}_p} & \text{if } v = p, \end{cases} \quad (3.10)$$

where $\{x\}_p$ is the fractional part of x in \mathbb{Q}_p . We extend it to a character χ_w on \mathbb{K}_w by setting $\chi_w := e_v \circ \mathrm{Tr}_{\mathbb{K}_w/\mathbb{Q}_v}$. The Haar measure du_w is the unique Haar measure on \mathbb{K}_w which is self dual with respect to χ_w . This is the Haar measure normalized such that the Fourier inversion holds.

3.2. (Co)homology of adelic spaces. For every real place σ of \mathbb{K} , let $\mathcal{V}_{\sigma} := \mathcal{V} \otimes_{\sigma} \mathbb{R}$ and $\mathcal{V}_{\mathbb{R}} := \bigoplus \mathcal{V}_{\sigma}$. It is a real quadratic space, and let (p_{σ}, q_{σ}) be its signature. Let \mathcal{D}_{σ}^{+} be the associated connected symmetric space, that can be described as one of the two connected components of the Grassmanian \mathcal{D}_{σ} of q_{σ} -dimensional oriented subspaces $z \subset \mathcal{V}_{\sigma}$ that are negative, *i.e.* $\mathcal{Q}|_z < 0$. We set $\mathcal{D}^{+} = \prod \mathcal{D}_{\sigma}^{+}$, where the product ranges over the archimedean places of \mathbb{K} for which $p_{\sigma}q_{\sigma}$ is nonzero¹. The dimension of \mathcal{D}_{σ}^{+} is $p_{\sigma}q_{\sigma}$, so that the dimension of \mathcal{D}^{+} is $\sum_{\sigma} p_{\sigma}q_{\sigma}$. At every place σ let \mathbb{K}_{σ} be the completion of \mathbb{K} , so that $\mathbb{K}_{\infty} \simeq \prod_{\sigma} \mathbb{K}_{\sigma}$. Since we assumed that \mathbb{K} only has real places, we have $\mathbb{K}_{\sigma} \simeq \mathbb{R}$. At the level of the orthogonal group, we have $\mathrm{SO}_{\mathcal{V}}(\mathbb{K}_{\infty}) \simeq \prod_{\sigma} \mathrm{SO}_{\mathcal{V}}(\mathbb{K}_{\sigma})$, where $\mathrm{SO}_{\mathcal{V}}(\mathbb{K}_{\sigma}) \simeq \mathrm{SO}(p_{\sigma}, q_{\sigma})$. The connected component $\mathrm{SO}_{\mathcal{V}}(\mathbb{K}_{\infty})^{+} \simeq \prod_{\sigma} \mathrm{SO}(p_{\sigma}, q_{\sigma})^{+}$ of the identity acts transitively on \mathcal{D}^{+} . Let K_{∞} be a maximal connected compact subgroup of $\mathrm{SO}_{\mathcal{V}}(\mathbb{K}_{\infty})^{+}$, that is isomorphic to $\prod_{\sigma} \mathrm{SO}(p_{\sigma}) \times \mathrm{SO}(q_{\sigma})$. Hence

$$\mathcal{D}^{+} \simeq \mathrm{SO}_{\mathcal{V}}(\mathbb{K}_{\infty})^{+} / K_{\infty} \simeq \prod_{\sigma} \mathrm{SO}(p_{\sigma}, q_{\sigma})^{+} / \mathrm{SO}(p_{\sigma}) \times \mathrm{SO}(q_{\sigma}). \quad (3.11)$$

Remark 3.2. Note that when $\mathbb{K} = \mathbb{Q}$ and $\mathcal{V} = V$, then for the unique real place we have $\mathcal{D}_{\sigma} = \mathcal{D}$, where

$$\mathcal{D} = \{(z, o) \mid z \subset V_{\mathbb{R}}, \dim(z) = q, \mathcal{Q}|_z < 0, o \text{ an orientation of } z\} \subset \mathrm{Gr}_q(V_{\mathbb{R}}) \quad (3.12)$$

is the space mentioned in the introduction. It has two connected components (corresponding to the two choices of orientations) and \mathcal{D}^{+} is one of them.

¹In the case where $p_{\sigma} = 0$ or $q_{\sigma} = 0$, the manifold \mathcal{D}_{σ}^{+} is just a point.

3.2.1. Let $\varphi_f \in \mathcal{S}(\mathcal{V}_{\mathbb{A}_{\mathbb{R},f}})$ be a finite Schwartz function, let $K_f \subset \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f})$ be an open compact preserving φ_f in the sense that $\omega(k, 1)\varphi_f = \varphi_f$. Let $K := K_{\infty}K_f$ and consider the adelic space

$$Y = \mathrm{SO}_{\mathcal{V}}(\mathbb{R}) \backslash \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R}}) / K \simeq \mathrm{SO}_{\mathcal{V}}(\mathbb{R}) \backslash \mathcal{D} \times \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f}) / K_f. \quad (3.13)$$

Let \mathcal{C} be the finite group of double cosets

$$\mathcal{C} := \mathrm{SO}_{\mathcal{V}}(\mathbb{R})^+ \backslash \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f}) / K_f. \quad (3.14)$$

Then we have

$$\mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f}) = \bigsqcup_{I \in \mathcal{C}} \mathrm{SO}_{\mathcal{V}}(\mathbb{R})^+ h_I K_f. \quad (3.15)$$

where $h_I \in \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f})$ are representants. The adelic space is a finite union of locally symmetric spaces

$$Y := \bigsqcup_{I \in \mathcal{C}} \Gamma_I \backslash \mathcal{D}^+ \quad (3.16)$$

where $\Gamma_I := h_I K_f h_I^{-1} \cap \mathrm{SO}_{\mathcal{V}}(\mathbb{R})^+$.

3.2.2. The space of differential r -forms on Y is defined by

$$\Omega^r(Y) := \bigoplus_{I \in \mathcal{C}} \Omega^r(\Gamma_I \backslash \mathcal{D}^+). \quad (3.17)$$

Let $C^\infty(\mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f}))$ be the space of locally constant functions on $\mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f})$. The map

$$[\Omega^r(\mathcal{D}^+) \otimes_{\mathbb{Q}} C^\infty(\mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f}))]^{(\mathrm{SO}_{\mathcal{V}}(\mathbb{R}) \times K_f)} \longrightarrow \Omega^r(Y) \quad (3.18)$$

sending $\eta \otimes f$ to $\sum_I f(h_I)\eta$ is an isomorphism, where $C^\infty(\mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R},f}))$ is the space of locally constant functions. We define the homology and cohomology of Y by

$$H^r(Y) := \bigoplus_{I \in \mathcal{C}} H^r(\Gamma_I \backslash \mathcal{D}^+), \quad H_r(Y) := \bigoplus_{I \in \mathcal{C}} H_r(\Gamma_I \backslash \mathcal{D}^+), \quad (3.19)$$

and similarly for the compactly supported cohomology. The integral of a closed form $\eta = \sum_{I \in \mathcal{C}} \eta_I$ over a cycle $C = \sum_{I \in \mathcal{C}} C_I$ in Y is then defined by

$$\int_C \eta = \sum_{I \in \mathcal{C}} \int_{C_I} \eta_I. \quad (3.20)$$

This pairing induces the Poincaré duality $H_r(Y) \simeq H^r(Y)^\vee \simeq H_c^{\dim(Y)-r}(Y)$.

For top degree forms, when $r = \dim(Y)$, the choice of an orientation ϱ gives an isomorphism

$$C^\infty(\mathrm{SO}_{\mathcal{V}}(\mathbb{R})^+)^{K_\infty} \longrightarrow \Omega^{\dim(Y)}(\mathcal{D}^+) \quad (3.21)$$

that sends a smooth K_∞ -invariant function f to a top degree form $f\varrho$. Combining the two isomorphisms (3.18) and (3.21), we get the following isomorphism for top degree forms

$$C^\infty(\mathrm{SO}_{\mathcal{V}}(\mathbb{R}) \backslash \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R}}))^{K_\infty} \longrightarrow \Omega^{\dim(Y)}(Y), \quad (3.22)$$

sending a function f to the form $\sum_{I \in \mathcal{C}} f(\cdot, h_I)\varrho$. When η is a top degree form, we can consider the integral over Y . Suppose that the form $\eta \in \Omega^{\dim(Y)}(Y)$ corresponds to a function f in the isomorphism (3.22). Then

$$\int_Y \eta = \frac{c}{\mathrm{vol}(K)} \int_{\mathrm{SO}_{\mathcal{V}}(\mathbb{R}) \backslash \mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R}})} f(g) dg \quad (3.23)$$

where $\mathrm{vol}(K)$ is the volume of K with respect to a Haar measure dg on $\mathrm{SO}_{\mathcal{V}}(\mathbb{A}_{\mathbb{R}})$, and $c > 0$ is a constant dependant on the choice of the Haar measure but independant of K . We suppose that the Haar measure is chosen such that $c = 1$.

3.3. Kudla-Millson theta lift. Let $(p, q) = \sum_{\sigma} (p_{\sigma}, q_{\sigma})$ be the signature of $\mathcal{V}_{\mathbb{R}} = \bigoplus \mathcal{V}_{\sigma}$. In [KM86; KM87] Kudla and Millson define a form

$$\varphi_{\text{KM}} \in \Omega^q(\mathcal{D}^+, \mathcal{S}(\mathcal{V}_{\mathbb{R}}))^{\text{SO}_{\mathcal{V}}(\mathcal{K}_{\infty})^+} \simeq [\Omega^q(\mathcal{D}^+) \otimes \mathcal{S}(\mathcal{V}_{\mathbb{R}})]^{\text{SO}_{\mathcal{V}}(\mathcal{K}_{\infty})^+} \quad (3.24)$$

valued in the Schwartz space $\mathcal{S}(\mathcal{V}_{\mathbb{R}})$. More precisely, at every place σ there is a form $\varphi_{\text{KM}}^{\sigma} \in \Omega^{q_{\sigma}}(\mathcal{D}_{\sigma}^+, \mathcal{S}(\mathcal{V}_{\sigma}))^{\text{SO}_{\mathcal{V}}(\mathcal{K}_{\sigma})^+}$ such that $\varphi_{\text{KM}}(v) = \bigwedge_{\sigma=1}^k \varphi_{\text{KM}}^{\sigma}(\sigma(v))$. These forms (hence also φ_{KM}) are closed *i.e.* $d\varphi_{\text{KM}}^{\sigma}(v) = 0$ for any v in \mathcal{V} , and $\text{SO}_{\mathcal{V}}(\mathcal{K}_{\sigma})^+$ -invariant in the sense that

$$h^* \varphi_{\text{KM}}^{\sigma}(v) = \varphi_{\text{KM}}^{\sigma}(h^{-1}v) \quad (3.25)$$

for any h in $\text{SO}_{\mathcal{V}}(\mathcal{K}_{\sigma})^+$ and v in \mathcal{V} . This extends to the invariance property

$$h^* \varphi_{\text{KM}}(v) = \varphi_{\text{KM}}(h^{-1}v) \quad (3.26)$$

for any h in $\text{SO}_{\mathcal{V}}(\mathcal{K}_{\infty})^+$. In particular, the Kudla-Millson form is $\text{SO}_{\mathcal{V}}(\mathcal{K})^+$ -invariant. Furthermore, it satisfies

$$\omega(k_{\theta}) \varphi_{\text{KM}} = \prod_{\sigma} e^{i\theta_{\sigma} m} \varphi_{\text{KM}} \quad (3.27)$$

where $m = \dim(\mathcal{V})$ and

$$k_{\theta} = \left(\begin{pmatrix} \cos(\theta_{\sigma}) & \sin(\theta_{\sigma}) \\ -\sin(\theta_{\sigma}) & \cos(\theta_{\sigma}) \end{pmatrix} \right)_{\sigma} \in \text{SO}(2)^k. \quad (3.28)$$

One of the main features of the Kudla-Millson form is its Thom form property. We will come back to this in Subsection 3.6.

3.3.1. Let us now define the Kudla-Millson theta series. Let $\varphi_f \in \mathcal{S}(\mathcal{V}_{\mathbb{A}_{\mathcal{K},f}})$ be the same Schwartz function as above, and let $K'_f \subset \text{SL}_2(\mathbb{A}_{\mathcal{K},f})$ be an open compact satisfying $\omega(1, k') \varphi_f(v) = \varphi_f(v)$ for every $k' \in K'_f$. Hence, the Schwartz function φ_f is $K_f \times K'_f$ invariant by the Weil representation. We define

$$\varphi := \varphi_{\text{KM}} \otimes \varphi_f \in \Omega^q(\mathcal{D}^+) \otimes \mathcal{S}(V_{\mathbb{A}_{\mathcal{K}}}) \quad (3.29)$$

For $g \in \text{SL}_2(\mathbb{A}_{\mathcal{K}})$ and $h_f \in \text{SO}_{\mathcal{V}}(\mathbb{A}_{\mathcal{K},f})$, the Kudla-Millson theta series is

$$\Theta_{\varphi}(g, h_f) := \sum_{v \in \mathcal{V}} (\omega(g, h_f) \varphi)(v) \in C^{\infty}(\text{SL}_2(\mathcal{K}) \backslash \text{SL}_2(\mathbb{A}_{\mathcal{K}})) \otimes \Omega^q(Y). \quad (3.30)$$

When g is fixed, we can view

$$\Theta_{\varphi}(g) := \Theta_{\varphi}(g, \cdot) \in \Omega^q(Y) \quad (3.31)$$

as a differential form on Y . Let $\Gamma'_{\mathcal{K}} := \text{SL}_2(\mathcal{K}) \cap K'_f$. For a point $(\tau_1, \dots, \tau_k) \in \mathcal{H}^k$ let $g_{\infty} = (g_{\tau_1}, \dots, g_{\tau_k}) \in \text{SL}_2(\mathbb{R})^k$ where

$$g_{\tau_{\sigma}} = \begin{pmatrix} \sqrt{y_{\sigma}} & x_{\sigma}/\sqrt{y_{\sigma}} \\ 0 & 1/\sqrt{y_{\sigma}} \end{pmatrix} \in \text{SL}_2(\mathbb{R}), \quad (3.32)$$

and $\tau_{\sigma} = x_{\sigma} + iy_{\sigma}$. Let

$$\Theta_{\varphi}(\tau_1, \dots, \tau_k) := (y_1 \cdots y_k)^{-\frac{m}{2}} \Theta_{\varphi}(g_{\infty}, \cdot) \in \Omega^q(Y), \quad (3.33)$$

where we recall that $m = \dim(\mathcal{V})$. By the work of Kudla and Millson - building on Weil's construction of automorphic forms - the form Θ_{φ} transforms like a Hilbert modular form of parallel weight m and level $\Gamma'_{\mathcal{K}} \subset \text{SL}_2(\mathcal{K})$, in the variables τ_1, \dots, τ_k . They also show that the form is holomorphic in cohomology, in the sense that for every σ we have

$$\frac{\partial}{\partial \bar{\tau}_{\sigma}} \Theta_{\varphi}(\tau_1, \dots, \tau_k) = d\eta_{\sigma} \quad (3.34)$$

for some $\eta_\sigma \in \Omega^{q-1}(Y)$. Furthermore, the form Θ_φ is closed, since φ_{KM} is. Hence, we can now view Θ_φ as an element

$$\Theta_\varphi \in H^q(Y) \otimes M_{(m, \dots, m)}(\Gamma'_\ell) \quad (3.35)$$

where $M_{(m, \dots, m)}(\Gamma'_\ell)$ is the space of Hilbert modular forms of parallel weight m and level $\Gamma'_\ell \subset \text{SL}_2(\ell)$. In particular, if $C \in \mathcal{Z}_q(Y)$ is a cycle, then

$$\begin{aligned} \Theta_\varphi(\tau_1, \dots, \tau_k, C) &= \int_C \Theta_\varphi(\tau_1, \dots, \tau_k) \\ &= \sum_{I \in \mathcal{C}} \int_{C_I} \Theta_\varphi(\tau_1, \dots, \tau_k, h_I) \in M_{(m, \dots, m)}(\Gamma'_\ell). \end{aligned} \quad (3.36)$$

Equivalently, if $\eta_C \in \Omega_c^{\dim(Y)-q}(Y)$ is a compactly supported form of complementary degree that is a Poincaré dual to C , then

$$\Theta_\varphi(\tau_1, \dots, \tau_k, C) = \int_Y \Theta_\varphi(\tau_1, \dots, \tau_k) \wedge \eta_C \in M_{(m, \dots, m)}(\Gamma'_\ell). \quad (3.37)$$

3.4. Restriction of scalars and seesaw. We can now consider the theta lift described in the previous paragraph in two cases.

Remark 3.3 (Remark on the notation). In section 3.1 we introduced the notations \mathcal{D} , Y and \mathcal{E} attached to the quadratic space \mathcal{V} where \mathcal{V} is either the quadratic space V over \mathbb{Q} or the quadratic space E over F . In the later case, we will replace the notation by \mathcal{D}_T , Y_T , \mathcal{E}_T and K_T , as used in the introduction. We will use the notations Θ_φ^V and Θ_φ^T if we need to emphasize the underlying dual pair.

3.4.1. First, let us consider the case where $\ell = \mathbb{Q}$ and $\mathcal{V} = V$. The symplectic space is $\mathcal{W} \simeq \mathbb{Q}^{4d}$ (recall that the degree of F is d). We have the Weil representation

$$\omega_V: \text{SL}_2(\mathbb{A}) \times \text{SO}_V(\mathbb{A}) \longrightarrow \mathcal{S}(V_\mathbb{A}). \quad (3.38)$$

Let $\varphi_f \in \mathcal{S}(V_{\mathbb{A}_f})$ a finite Schwartz function as previously. Let $\varphi = \varphi_{\text{KM}}^V \otimes \varphi_f$, where $\varphi_{\text{KM}}^V \in \Omega^q(\mathcal{D}^+)$ is the Kudla-Millson form on \mathcal{D}^+ . In this setting, the Kudla-Millson lift is

$$\Theta_\varphi: H_q(Y) \longrightarrow M_d(\Gamma'_\mathbb{Q}), \quad (3.39)$$

for some $\Gamma'_\mathbb{Q} \subset \text{SL}_2(\mathbb{Q})$ depending on φ_f .

3.4.2. Let us now consider the Kudla-Millson lift for the quadratic space $(\mathcal{V}, \mathcal{Q}) = (E, Q_\alpha)$. Let us consider subsections 3.1 and 3.2 in the setting of this quadratic space of dimension $m = 2$ over the totally real field $\ell = F$ of degree $k = d$. Recall that $\text{T}(\mathbb{Q}) \simeq E^1 \simeq \text{SO}_E(F)$.

The symplectic space is $\mathcal{W} \simeq F^4$, and we have a representation

$$\omega_E: \text{SL}_2(\mathbb{A}_F) \times \text{SO}_E(\mathbb{A}_F) \longrightarrow \mathcal{S}(\mathbb{A}_E). \quad (3.40)$$

Let $\text{T}(\mathbb{R})^+ \simeq \text{SO}_E(F_\mathbb{R})^+$ be the connected components of its real points. Since T is of maximal real rank, we have $E_\infty^{1,+} \simeq \text{T}(\mathbb{R})^+ \simeq (\mathbb{R}_{>0})^q \times (S^1)^{\frac{p-q}{2}}$ where S^1 is the unit circle. The maximal compact subgroup in $\text{T}(\mathbb{R})^+$ is $K_{T,\infty} \simeq (S^1)^{\frac{p-q}{2}}$, hence

$$\mathcal{D}_T^+ = \text{T}(\mathbb{R})^+ / K_{T,\infty} \simeq (\mathbb{R}_{>0})^q. \quad (3.41)$$

We can view the Schwartz function $\varphi_f \in \mathcal{S}(V_{\mathbb{A}_f})$ used for the lift (3.39) as a finite Schwartz function in $\varphi_f \in \mathcal{S}(\mathbb{A}_{E,f})$ and set $\varphi = \varphi_{\text{KM}}^E \otimes \varphi_f$, where $\varphi_{\text{KM}}^E \in \Omega^q(\mathcal{D}_T^+) \simeq \Omega^q(\mathbb{R}_{>0}^q)$ is the Kudla-Millson form on \mathcal{D}_T^+ .

Let $K_{T,f} \times K'_{T,f} \subset \text{SO}_E(\mathbb{A}_{F,f}) \times \text{SL}_2(\mathbb{A}_{F,f})$ be the open compacts stabilizing φ under the Weil representation, and let Y_T the locally symmetric space. Let \mathcal{E}_T be the finite group of double cosets

$$\mathcal{E}_T := \text{T}(\mathbb{Q})^+ \backslash \text{T}(\mathbb{A}_f) / K_{T,f} = E^{1,+} \backslash \mathbb{A}_{E,f}^1 / K_{T,f} \quad (3.42)$$

where $E^{1,+} = E^1 \cap (E_\infty^1)^+ \simeq \mathrm{T}(\mathbb{Q}) \cap \mathrm{T}(\mathbb{R})^+$ is the intersection with the connected component of the identity. The space

$$Y_T = \mathrm{T}(\mathbb{Q}) \backslash \mathrm{T}(\mathbb{A}) / K_T \simeq E^1 \backslash E_\mathbb{A}^1 / K_T \simeq E^1 \backslash ((\mathbb{R}_{>0})^q \times \mathbb{A}_{E,f}^1) / K_{T,f} \quad (3.43)$$

is a disjoint union of connected components

$$Y_T = \bigsqcup_{I \in \mathcal{C}_T} \Lambda \backslash \mathbb{R}_{>0}^q. \quad (3.44)$$

where $\Lambda := \mathrm{T}(\mathbb{Q})^+ \cap K_{T,f}$. By [PR94, Theorem. 4.11, p. 208], the quotient Y_T is compact since $\mathrm{T}(\mathbb{Q}) \simeq E^1$ is \mathbb{Q} -anisotropic. Then $\dim(Y_T) = q$ and the Kudla-Millson theta lift is

$$\Theta_\varphi^T: H_q(Y_T) \longrightarrow M_{(1,\dots,1)}(\Gamma'_F), \quad (3.45)$$

where $\Gamma'_F \subset \mathrm{SL}_2(F)$.

We have $H_q(Y_T, \mathbb{C}) \simeq \mathbb{C}[\mathcal{C}_T]$. Let $Y_{T,I}$ be the connected component corresponding to I in (3.44) and $[Y_{T,I}] \in H_q(Y_{T,I})$ a fundamental class, i.e. a generator of $H_q(Y_{T,I}, \mathbb{Z}) \simeq \mathbb{Z}$. Let χ_f be the finite part of the Hecke character and suppose that χ_f is trivial on $K_{T,f}$. Hence, we can view χ_f as a function on \mathcal{C}_T and define

$$[Y_\chi] := \sum_{I \in \mathcal{C}_T} \chi_f(I) Y_{T,I} \in H_q(Y_T, \mathbb{C}). \quad (3.46)$$

We define the image of this class to be

$$\Theta_\varphi^T(\tau_1, \dots, \tau_d, \chi) := \int_{Y_\chi} \Theta_\varphi^T(\tau_1, \dots, \tau_d) \in M_{(1,\dots,1)}(\Gamma'_F). \quad (3.47)$$

Note that $\mathcal{D}_T^+ \simeq \mathrm{SO}_E(\mathbb{R})^+ \simeq (\mathbb{R}_{>0})^q$. By (3.22), the orientation $dt^\times := dt_1^\times \wedge \dots \wedge dt_q^\times$ of \mathcal{D}_T^+ , where $dt_\sigma^\times = \frac{dt_\sigma}{t_\sigma}$, identifies

$$C^\infty(\mathrm{T}(\mathbb{Q}) \backslash \mathrm{T}(\mathbb{A}))^{K_T} \simeq \Omega^q(Y_T). \quad (3.48)$$

Hence, we can write

$$\Theta_\varphi^T(\tau_1, \dots, \tau_d) = \tilde{\Theta}_\varphi^T(\tau_1, \dots, \tau_d, t) dt^\times \in \Omega^q(Y_T) \quad (3.49)$$

for some smooth function $\tilde{\Theta}_\varphi^T(\tau_1, \dots, \tau_d, \cdot) \in C^\infty(\mathrm{T}(\mathbb{Q}) \backslash \mathrm{T}(\mathbb{A}))^{K_T}$. We can also write (3.47) as

$$\Theta_\varphi^T(\tau_1, \dots, \tau_d, \chi) = \frac{1}{\mathrm{vol}(K_T)} \int_{\mathrm{T}(\mathbb{Q}) \backslash \mathrm{T}(\mathbb{A})} \tilde{\Theta}_\varphi^T(\tau_1, \dots, \tau_d, t) \chi(t) dt^\times \in M_{(1,\dots,1)}(\Gamma'_F), \quad (3.50)$$

where $\mathrm{vol}(K_T)$ is the volume with respect to the Haar measure dt^\times on $\mathrm{T}(\mathbb{A}) \simeq E_\mathbb{A}^1$.

3.4.3. The seesaw identity is a way to relate the lifts (3.45) and (3.39). By restriction of scalars from F to \mathbb{Q} , we can embed $\mathrm{Sp}_4(F)$ in $\mathrm{Sp}_{4d}(\mathbb{Q})$, as well as the subgroups forming the dual pair $\mathrm{SL}_2(\mathbb{A}_F) \times \mathrm{SO}_E(\mathbb{A}_F)$. The image of these two subgroups satisfy $\mathrm{SL}_2(\mathbb{Q}) \subset \mathrm{SL}_2(F)$ and $\mathrm{SO}_E(F) \subset \mathrm{SO}_V(\mathbb{Q})$, where the latter inclusion is restriction of scalars. For the former embedding of $\mathrm{SL}_2(F)$ in $\mathrm{Sp}_{4d}(\mathbb{Q})$, it is given by

$$\begin{array}{ccc} \mathrm{SL}_2(F) & \hookrightarrow & \mathrm{Sp}_{4d}(\mathbb{Q}) \\ \begin{pmatrix} a & b \\ c & d \end{pmatrix} & \longmapsto & \begin{pmatrix} r(a) & r(b) \\ r(c) & r(d) \end{pmatrix} \end{array} \quad (3.51)$$

where $r: F^\times \longrightarrow \mathrm{GL}_d(\mathbb{Q})$ is the regular representation. These two dual pairs form the seesaw

$$\begin{array}{ccc} \mathrm{SO}_V(\mathbb{Q}) & & \mathrm{SL}_2(F) \\ | & \searrow & | \\ \mathrm{SO}_E(F) & & \mathrm{SL}_2(\mathbb{Q}). \end{array}$$

We also had the pairs of open compact subgroups $K_f \times K'_f \subset \mathrm{SO}_V(\mathbb{A}_f) \times \mathrm{SL}_2(\mathbb{A}_f)$ and $K_{T,f} \times K'_{T,f} \subset \mathrm{SO}_E(\mathbb{A}_{F,f}) \times \mathrm{SL}_2(\mathbb{A}_{F,f})$ stabilizing φ_f . Suppose they are compatible with the embeddings in the sense that $K_{T,f} \subset K_f \cap \mathrm{SO}_E(\mathbb{A}_{F,f})$ and $K'_f \subset K'_{T,f} \cap \mathrm{SL}_2(\mathbb{A}_f)$. After conjugating if necessary, we can assume that the maximal compacts K_∞ and $K_{T,\infty}$ are chosen such that $K_\infty \cap \mathrm{SO}_V(\mathbb{R})^+ = K_{T,\infty}$. Then the embedding of SO_E in SO_V induces an immersion

$$\phi: Y_T \longrightarrow Y. \quad (3.52)$$

This immersion induces a pullback in cohomology

$$\phi^*: H^q(Y, \mathbb{C}) \longrightarrow H^q(Y_T, \mathbb{C}), \quad (3.53)$$

and a pushforward in homology

$$\phi_*: H_q(Y_T, \mathbb{C}) \longrightarrow H_q(Y, \mathbb{C}). \quad (3.54)$$

On the other hand, the pullback by the diagonal inclusion of \mathcal{H} in $\mathcal{H}^d = \mathcal{H} \times \cdots \times \mathcal{H}$ induces the diagonal restriction

$$\iota^*: M_{(1,\dots,1)}(\Gamma'_F) \longrightarrow M_d(\Gamma'_F \cap \mathrm{SL}_2(\mathbb{Q})). \quad (3.55)$$

Note that $\Gamma'_\mathbb{Q} \subset \Gamma'_F \cap \mathrm{SL}_2(\mathbb{Q})$ by the assumption on the compact groups K'_f and $K'_{T,f}$. The seesaw identity relies on two observations. Firstly, the two Weil representations ω_V and ω_E agree on their smallest common subgroups of both dual pairs, namely $(\mathrm{SO}_E(F), \mathrm{SL}_2(\mathbb{Q}))$. Secondly, the Kudla-Millson form has the functorial property that $\varphi_{\mathrm{KM}}^V|_{\mathcal{D}_T^+} = \varphi_{\mathrm{KM}}^E$, see [Bra23b, Equation. (5.10)]. Hence, the two kernels

$$\Theta_\varphi^V \in C^\infty(\mathcal{H}) \otimes \Omega^q(Y) \quad (3.56)$$

and

$$\Theta_\varphi^T \in C^\infty(\mathcal{H}^d) \otimes \Omega^q(Y_T) \quad (3.57)$$

for E and V respectively, agree when restricted to

$$C^\infty(\mathcal{H}) \otimes \Omega^q(Y_T). \quad (3.58)$$

We deduce the seesaw identity

$$\iota^* \Theta_\varphi^T = \phi^* \Theta_\varphi^V. \quad (3.59)$$

3.4.4. For a class I in the class group \mathcal{C}_T of T we define the toric cycle

$$C_{T,I} = \phi_* Y_{T,I} \in H_q(Y, \mathbb{Z}) \quad (3.60)$$

to be the pushforward of the fundamental class. We also define

$$C_\chi := \phi_* Y_\chi = \sum_{I \in \mathcal{C}_T} \chi_f(I) C_{T,I} \in H_q(Y, \mathbb{Z}). \quad (3.61)$$

We then have

$$\Theta_\varphi^T(\tau, \dots, \tau, \chi) = \int_{Y_\chi} \Theta_\varphi^T(\tau, \dots, \tau) = \int_{Y_\chi} \phi^* \Theta_\varphi^V(\tau) = \int_{\phi_* Y_\chi} \Theta_\varphi^V(\tau), \quad (3.62)$$

which gives the seesaw identity

$$\Theta_\varphi^T(\tau, \dots, \tau, \chi) = \int_{C_\chi} \Theta_\varphi^V(\tau). \quad (3.63)$$

3.4.5. For now we have only considered the case where E is an extension of a field F , but we want to consider more general étale algebras of the form $E = E_1 \times \cdots \times E_r$, together with an involution fixing $F = F_1 \times \cdots \times F_r$. Here each of the F_i is a totally real field of degree d_i , that is the fixed field of E_i . Suppose that (V, Q) is the restriction of scalars of (E, Q_α) from F to \mathbb{Q} , as in 2.1. Then V is a vector space of dimension $2d$ where $d = d_1 + \cdots + d_r$. Furthermore, we can split the quadratic space as $V = V_1 \oplus \cdots \oplus V_r$, where V_i is the restriction of scalars of E_i from the field F_i to \mathbb{Q} . We can restrict the embedding $\mathrm{SO}_V(\mathbb{Q}) \hookrightarrow \mathrm{Sp}_{4d}(\mathbb{Q})$ given in 3.4 to an embedding $\mathrm{SO}_{V_1}(\mathbb{Q}) \times \cdots \times \mathrm{SO}_{V_r}(\mathbb{Q}) \hookrightarrow \mathrm{Sp}_{4d}(\mathbb{Q})$. Its commutator is $\mathrm{SL}_2(\mathbb{Q})^r$ and we get a seesaw

$$\begin{array}{ccc} \mathrm{SO}_V(\mathbb{Q}) & & \mathrm{SL}_2(\mathbb{Q})^r \\ | & \searrow & \swarrow \\ \mathrm{SO}_{V_1}(\mathbb{Q}) \times \cdots \times \mathrm{SO}_{V_r}(\mathbb{Q}) & & \mathrm{SL}_2(\mathbb{Q}). \end{array}$$

Combining with previous seesaw, we then get

$$\begin{array}{ccc} \mathrm{SO}_V(\mathbb{Q}) & & \mathrm{SL}_2(F_1) \times \cdots \times \mathrm{SL}_2(F_r) \\ | & \searrow & \swarrow \\ \mathrm{SO}_{E_1}(F_1) \times \cdots \times \mathrm{SO}_{E_r}(F_1) & & \mathrm{SL}_2(\mathbb{Q}). \end{array}$$

Let $\varphi_f \in \mathcal{S}(V_{\mathbb{A}_f})$ be a finite Schwartz function. Let $\varphi = \varphi_{\mathrm{KM}}^V \otimes \varphi_f$ and the associated theta lift

$$\Theta_\varphi^V: H^q(Y, \mathbb{C}) \longrightarrow M_d(\Gamma'_\mathbb{Q}). \quad (3.64)$$

We have $\mathcal{S}(V_{\mathbb{A}_f}) \simeq \mathcal{S}(\mathbb{A}_{E,f}) \simeq \mathcal{S}(\mathbb{A}_{E_1,f}) \otimes \cdots \otimes \mathcal{S}(\mathbb{A}_{E_r,f})$ and so we can write φ_f as a finite sum

$$\varphi_f = \sum_{\beta} \varphi_f^{\beta,1} \otimes \cdots \otimes \varphi_f^{\beta,r} \quad (3.65)$$

with $\varphi_f^{\beta,i} \in \mathcal{S}(\mathbb{A}_{E_i,f})$. Similarly, the character χ on $\mathrm{T}(\mathbb{Q}) \backslash \mathrm{T}(\mathbb{A})$ can be written as $\chi = \chi_1 \times \cdots \times \chi_r$ where

$$\chi_i: \mathrm{T}_i(\mathbb{Q}) \backslash \mathrm{T}_i(\mathbb{A}) \longrightarrow \mathbb{C}^\times \quad (3.66)$$

and $\mathrm{T}_i(\mathbb{Q}) \simeq E_i^1$. We set $\varphi^{\beta,i} = \varphi_{\mathrm{KM}}^{E_i} \otimes \varphi_f^{\beta,i}$, and as above we get a Hilbert modular form

$$\Theta_{\varphi^{\beta,i}}(\tau_1, \dots, \tau_d, \chi_i) \in M_{(1,\dots,1)}(\Gamma'_i) \quad (3.67)$$

of parallel weight one for a congruence subgroup Γ'_i of $\mathrm{SL}_2(F_i)$. We denote by

$$\Theta_{\varphi^{\beta,i}}(\tau^\Delta, \chi_i) = \Theta_{\varphi^{\beta,i}}(\tau, \dots, \tau, \chi_i) \in M_{d_i}(\Gamma'_i \cap \mathrm{SL}_2(\mathbb{Q})) \quad (3.68)$$

its diagonal restriction, which is a modular form of weight d_i .

By the functoriality of the Kudla-Millson we have

$$\varphi_{\mathrm{KM}}^V|_{Y_{E_1} \times \cdots \times Y_{E_r}} = \varphi_{\mathrm{KM}}^{E_1} \wedge \cdots \wedge \varphi_{\mathrm{KM}}^{E_r}. \quad (3.69)$$

We can deduce the following from Proposition 3.63.

Proposition 3.1. *We have the seesaw identity*

$$\int_{C_\chi} \Theta_\varphi^V(\tau) = \sum_{\beta} \Theta_{\varphi^{\beta,1}}(\tau^\Delta, \chi_1) \cdots \Theta_{\varphi^{\beta,r}}(\tau^\Delta, \chi_r). \quad (3.70)$$

3.5. Computations of the Hilbert modular form. Let us compute the Kudla-Millson form

$$\varphi_{\mathrm{KM}}^E = \varphi_{\mathrm{KM}}^V|_{\mathcal{D}_T^+} \in \Omega^q(\mathcal{D}_T^+). \quad (3.71)$$

Suppose that E is a field. Since T is of maximal real rank, S_3 is empty by Proposition 2.6. Recall that $q = |S_1|$ by Proposition 2.6. At a place $\sigma \in S_2$, the algebra is $E_\sigma \simeq \mathbb{C}$ and the space \mathcal{D}_σ^+ is a point. So the Kudla-Millson form is of degree 0 and is simply the Gaussian

$$\varphi_{\text{KM}}^\sigma(v) = e^{-\pi|\alpha_\sigma|N_{E_\sigma/F_\sigma}(v)} \in \Omega^0(\mathcal{D}_\sigma^+). \quad (3.72)$$

At a place $\sigma \in S_1$, the algebra is $E_\sigma \simeq \mathbb{R} \times \mathbb{R}$ and $\mathcal{D}_\sigma^+ \simeq \mathbb{R}_{>0}$. An element v in E_σ is sent to (v_σ, v'_σ) in E_σ . The Kudla-Millson form (see [Bra23b]) is given by

$$\varphi_{\text{KM}}^\sigma(v) = \sqrt{|\alpha_\sigma|} e^{-\pi|\alpha_\sigma|((v_\sigma t_\sigma^{-1})^2 + (t_\sigma v'_\sigma)^2)} \left(\frac{v_\sigma}{t_\sigma} + t_\sigma v'_\sigma \right) \frac{dt_\sigma}{t_\sigma} \in \Omega^1(\mathcal{D}_\sigma^+) \quad (3.73)$$

for $v \in E_\sigma$.

3.5.1. We define a Schwartz function $\varphi_\infty \in \mathcal{S}(E_\mathbb{R})$ by $\varphi_\infty = \prod_\sigma \varphi_\sigma$ where $\varphi_\sigma = \varphi_{\text{KM}}^\sigma$ when σ is in S_2 , and

$$\varphi_\sigma(x, x') := \sqrt{|\alpha_\sigma|} e^{-\pi|\alpha_\sigma|(x^2 + (x')^2)} (x + x'). \quad (3.74)$$

when σ is in S_1 . Then, under the isomorphism $C^\infty(\mathbb{R}_>^q) \simeq \Omega^q(\mathcal{D}_T^+)$, we

$$(\omega(g_\infty, 1)\varphi_{\text{KM}}^E)(v) = (\omega(g_\infty, t_\infty)\varphi_\infty)(v) dt_\infty^\times \quad (3.75)$$

for $g_\infty \in \text{SL}_2(F_\mathbb{R})$. Note that since E is a field, any nonzero $v \in E$ must satisfy $v_\sigma v'_\sigma \neq 0$ at any place $\sigma \in S_1$. Let $\tau := (\tau_\sigma)_\sigma \in \mathcal{H}^d$ be the image of (i, \dots, i) by g_∞ and write

$$\text{Tr}_{F/\mathbb{Q}}(\tau m) := \sum_\sigma \tau_\sigma m_\sigma \quad (3.76)$$

for $m \in F$. The following Lemma is a classical computation. A similar computation appears in Kudla's work [Kud81], and even Hecke's original paper [Hec27].

Lemma 3.2. *Suppose that E/F is a field extension. We have*

$$\int_{E_\infty^1} \omega(g_\infty, t_\infty) \varphi_\infty(v) \chi_\infty(t) dt_\infty^\times = 2^q (y_1 \cdots y_d)^{\frac{1}{2}} \left(\prod_{\sigma \in S_1} \text{sgn}(v_\sigma + v'_\sigma) \right) e^{2i\pi \text{Tr}_{F/\mathbb{Q}}(\tau \alpha m)}$$

if $m = N_{E/F}(v)$ is totally positive, and the integral is 0 otherwise.

Proof. At a place σ in S_2 there is no integral, since \mathcal{D}_σ^+ is a point. At a place σ in S_1 we have

$$\begin{aligned} \int_{E_\sigma^1} \omega(1, t_\sigma) \varphi_\sigma(v_\sigma, v'_\sigma) \chi_\sigma(t_\sigma) dt_\sigma^\times &= \sqrt{|\alpha_\sigma|} \int_{\mathbb{R}^\times} e^{-\pi|\alpha_\sigma|((v_\sigma t_\sigma^{-1})^2 + (t_\sigma v'_\sigma)^2)} \left(\frac{v_\sigma}{t_\sigma} + t_\sigma v'_\sigma \right) \text{sgn}_\sigma(t_\sigma) \frac{dt_\sigma}{t_\sigma} \\ &= 2\sqrt{|a_\sigma v_\sigma v'_\sigma|} \int_0^\infty e^{-\pi|a_\sigma v_\sigma v'_\sigma|(u^{-2} + u^2)} \left(\frac{\text{sgn}(v_\sigma)}{u} + \text{sgn}(v'_\sigma)u \right) \frac{du}{u} \end{aligned}$$

after the substitution $t_\sigma = \sqrt{\left| \frac{v_\sigma}{v'_\sigma} \right|} u$. Note that the assumption that $\chi_\sigma(t_\sigma) = \text{sgn}(t_\sigma)$ is crucial here, since the integral would be 0 otherwise. After substituting $\beta = u^2$ we find that this integral is

$$K_{\frac{1}{2}}(2\pi|\alpha_\sigma v_\sigma v'_\sigma|) \sqrt{|\alpha_\sigma v_\sigma v'_\sigma|} \text{sgn}(v_\sigma + v'_\sigma) \quad (3.77)$$

where $K_s(w) = \int_0^\infty e^{-w(\beta^{-1} + \beta)} \beta^s \frac{d\beta}{\beta}$ is the K -Bessel function. We deduce that the integral vanishes when $m_\sigma = v_\sigma v'_\sigma$ is negative at some place *i.e.* when m is not totally positive. Using the fact that $K_{\frac{1}{2}}(w) = \sqrt{\frac{2\pi}{w}} e^{-w}$, equation (3.77) becomes

$$2 \text{sgn}(v_\sigma + v'_\sigma) e^{-2\pi|\alpha_\sigma v_\sigma v'_\sigma|} \quad (3.78)$$

Thus, taking the product over all the places of F we get

$$\int_{E_\infty^1} \omega(1, t_\infty) \varphi_\infty(v) \chi_\infty(t) dt_\infty^\times = 2^q \left(\prod_{\sigma \in S_1} \text{sgn}(v_\sigma + v'_\sigma) \right) \prod_{\sigma \in S_1 \cup S_2} e^{-2\pi|\alpha_\sigma v_\sigma v'_\sigma|}. \quad (3.79)$$

□

3.5.2. Recall that we can write

$$\Theta_\varphi^T(\tau_1, \dots, \tau_d) = \tilde{\Theta}_\varphi^T(\tau_1, \dots, \tau_d, t) dt^\times \in \Omega^q(Y_T). \quad (3.80)$$

By (3.75) we have

$$\tilde{\Theta}_\varphi^T(\tau_1, \dots, \tau_d, t) = (y_1 \cdots y_d)^{-\frac{1}{2}} \sum_{v \in E} (\omega(g_\infty, t)\varphi)(v) \quad (3.81)$$

where $\varphi = \varphi_\infty \otimes \varphi_f \in \mathcal{S}(\mathbb{A}_E)$ is as above. We get

$$\begin{aligned} \Theta_\varphi^T(\tau_1, \dots, \tau_d, \chi) &= \frac{2^q}{\text{vol}(K_T)} \int_{E^1 \setminus E_\mathbb{A}^1} (y_1 \cdots y_d)^{-\frac{1}{2}} \sum_{v \in E} (\omega(g_\infty, t)\varphi)(v) \chi(t) dt^\times \\ &= \frac{2^q}{\text{vol}(K_T)} (y_1 \cdots y_d)^{-\frac{1}{2}} \sum_{v \in E^1 \setminus E} \int_{E_\mathbb{A}^1} (\omega(g_\infty, t)\varphi)(v) \chi(t) dt^\times \\ &= \sum_{m \in F} c_\varphi^{(m)}(C_\chi) e^{2i\pi \text{Tr}_{F/\mathbb{Q}}(\tau \alpha m)} \end{aligned} \quad (3.82)$$

where

$$\begin{aligned} c_\varphi^{(m)}(C_\chi) &:= \frac{2^q}{\text{vol}(K_T)} \sum_{\substack{v \in E^1 \setminus E \\ N_{E/F}(v)=m}} \int_{E_\mathbb{A}^1} (\omega(g_\infty, t)\varphi)(v) \chi(t) dt^\times \\ &= \frac{2^q}{\text{vol}(K_T)} \sum_{\substack{v \in E^1 \setminus E \\ N_{E/F}(v)=m}} \left(\prod_{\sigma \in S_1} \text{sgn}(v_\sigma + v'_\sigma) \right) \int_{\mathbb{A}_{E,f}^1} \varphi_f(t^{-1}v) \chi_f(t) dt^\times. \end{aligned} \quad (3.83)$$

Note that $c_\varphi^{(m)}(C_\chi)$ is nonzero only if m is totally positive.

Theorem 3.3. *Let χ be a character on a anisotropic maximal \mathbb{Q} -torus T of maximal real rank. Then $\Theta_\varphi^V(\tau, C_\chi)$ is a cusp form.*

Proof. Suppose that F is a field, and E a quadratic field extension. Then the only $v \in E$ for which $Q_\alpha(v, v) = N_{E/F}(v, v) = 0$ is $v = 0$. Since $v_\sigma = v'_\sigma = 0$, we see from (3.83) that the constant term $c_\varphi^{(0)}(C_\chi)$ is zero.

If E/F is a product of field extensions E_i/F_i , then by Proposition 3.1 the constant term is

$$c_\varphi^{(0)}(C_\chi) = \sum_{\beta} c_{\varphi^{\beta,1}}^{(0)}(C_{\chi_1}) \cdots c_{\varphi^{\beta,r}}^{(0)}(C_{\chi_r}). \quad (3.84)$$

In particular, there must be one of the fields F_i that has a place $\sigma \in S_1$. For this index i , the constant term $c_{\varphi^{\beta,i}}^{(0)}(C_{\chi_i})$ is zero for any β . Hence (3.84) vanishes. \square

3.6. Generating series of intersection numbers. Let (V, Q) be a quadratic space of even dimension $2d$ over \mathbb{Q} . Let L be an even integral lattice and $\varphi_f = \mathbf{1}_{\hat{L}} \in \mathcal{S}(V_{\mathbb{A}_f})$ its characteristic function. We describe the geometric features of the Kudla-Millson form, that allows us to have a nice geometric interpretation of Kudla-Millson lift $\Theta_\varphi(\tau, C)$ defined in (3.36).

3.6.1. Any vector v in V with $Q(v, v) > 0$ defines a submanifold of codimension q

$$\mathcal{D}_v^+ := \{z \in \mathcal{D}^+ \mid z \subset v^\perp\}. \quad (3.85)$$

For every I in the group \mathcal{C} of double cosets

$$\mathcal{C} = \text{SO}_V(\mathbb{Q})^+ \backslash \text{SO}_V(\mathbb{A}_f) / K_f \quad (3.86)$$

let $\Gamma_{I,v}$ be the stabilizer of v in Γ_I . We denote by $C_v(h_I)$ the image of the composition

$$\Gamma_{I,v} \backslash \mathcal{D}_v^+ \hookrightarrow \Gamma_{I,v} \backslash \mathcal{D}^+ \longrightarrow \Gamma_I \backslash \mathcal{D}^+ =: Y_I. \quad (3.87)$$

Note that $C_v(h_I)$ only depends on the orbit of $\Gamma_I v$. For a positive number $n \in \mathbb{Q}$, we define the weighted cycles

$$C_n(\varphi_f, h_I) := \sum_{\substack{v \in \Gamma_I \backslash V \\ Q(v,v)=2n}} \varphi_f(h_I^{-1}v) C_v(h_I) \in \mathcal{X}_{pq-q}(Y_I, \partial Y_I, \mathbb{Z}) \quad (3.88)$$

and

$$C_n(\varphi) := \sum_{I \in \mathcal{C}} C_n(\varphi_f, h_I) \in \mathcal{X}_{pq-q}(Y, \partial Y, \mathbb{Z}). \quad (3.89)$$

Note that since L is assumed to be integral, the cycle $C_n(\varphi)$ is only nonzero for $n \in \mathbb{N}_{>0}$.

3.6.2. Let us go back to the Kudla-Millson form introduced in 3.3 and described its geometric features. Recall that the Kudla-Millson

$$\varphi_{\text{KM}} \in \Omega^q(\mathcal{D}^+, \mathcal{S}(V_{\mathbb{R}}))^{\text{SO}_V(\mathbb{R})^+} \simeq [\Omega^q(\mathcal{D}^+) \otimes \mathcal{S}(V_{\mathbb{R}})]^{\text{SO}_V(\mathbb{R})^+} \quad (3.90)$$

is a closed and $\text{SO}_V(\mathbb{R})^+$ -invariant on \mathcal{D}^+ . In particular, if $\Gamma = \Gamma_I$ (for some $I \in \mathcal{C}$) is a congruence subgroup of $\text{SO}_V(\mathbb{Q})^+$, then the form φ_{KM} is Γ_v -invariant, where Γ_v is the stabilizer of v in Γ . Hence, it descends to a form on $\Gamma_v \backslash \mathcal{D}^+$.

The main geometric feature of the Kudla-Millson form is the following Thom form property. Let v be a positive vector. For any compactly supported form $\omega \in \Omega_c^{pq-q}(\Gamma_v \backslash \mathcal{D}^+)$ of complementary degree we have

$$\int_{\Gamma_v \backslash \mathcal{D}^+} \varphi_{\text{KM}}(v) \wedge \omega = e^{-\pi Q(v,v)} \int_{\Gamma_v \backslash \mathcal{D}_v^+} \omega. \quad (3.91)$$

In other words, the form

$$\varphi^0(v) := e^{\pi Q(v,v)} \varphi_{\text{KM}}(v) \quad (3.92)$$

is a Poincaré dual to $\Gamma_v \backslash \mathcal{D}_v^+$ in $\Gamma_v \backslash \mathcal{D}^+$.

3.6.3. Note that for $g_\tau = \begin{pmatrix} \sqrt{y} & \frac{x}{\sqrt{y}} \\ 0 & \frac{1}{\sqrt{y}} \end{pmatrix}$ we have

$$(\omega(g_\tau) \varphi_{\text{KM}})(\tau) = y^{\frac{p+q}{2}} \varphi_{\text{KM}}(\sqrt{y}v) e^{i\pi x Q(v,v)} = y^{\frac{p+q}{2}} \varphi^0(\sqrt{y}v) e^{i\pi \tau Q(v,v)}. \quad (3.93)$$

We can rewrite the theta series (3.33) as

$$\Theta_\varphi(\tau) = y^{-\frac{p+q}{2}} \sum_{v \in V} (\omega(g_\tau) \varphi)(v) = \sum_{n \in \mathbb{Q}} \Theta_\varphi^{(n)}(\tau) q^n \quad (3.94)$$

by grouping the vectors of same length, where

$$\Theta_\varphi^{(n)}(\tau) := \sum_{\substack{v \in V \\ Q(v,v)=2n}} \varphi^0(\sqrt{y}v) \varphi_f(v) = \sum_{\substack{v \in L \\ Q(v,v)=2n}} \varphi^0(\sqrt{y}v). \quad (3.95)$$

The form $\Theta_\varphi^{(n)}(\tau)$ is closed, and for positive n it represents a Poincaré dual of the special cycle $C_n(\varphi)$ in $H^q(Y, \mathbb{C})$. For negative n , the form is exact. When V is anisotropic, the constant term is $\varphi_0(0) \varphi_f(0)$ where $\varphi_0(0)$ represents the Euler class of the tautological bundle over \mathcal{D}^+ .

By the work of Kudla and Millson, if C is a class in $H_q(Y, \mathbb{Z})$ then the period

$$\Theta_\varphi^V(\tau, C) = \int_C \Theta_\varphi^V(\tau) \quad (3.96)$$

is a modular form of weight $d = \frac{p+q}{2}$ of level $\Gamma_0(N)$. Since $\Theta_\varphi^{(n)}(\tau)$ is a Poincaré dual to $C_n(\varphi)$, we get that

$$\int_C \Theta_\varphi^V(\tau) = c_\varphi^0(C) + \sum_{n=1}^{\infty} \int_C \Theta_\varphi^{(n)}(\tau) q^n = c_\varphi^0(C) + \sum_{n \in \mathbb{Q}_{>0}} \langle C, C_n(\varphi) \rangle q^n. \quad (3.97)$$

When the cycles C and $C_n(\varphi)$ intersect transversely, then $\langle C, C_n(\varphi) \rangle$ is the signed intersection number.

3.6.4. Let $E = E_1 \times \cdots \times E_r$ with fixed subalgebra $F = F_1 \times \cdots \times F_r$. So the torus is a product $T(\mathbb{Q}) = T_1(\mathbb{Q}) \times \cdots \times T_r(\mathbb{Q})$ where $T_i(\mathbb{Q}) \simeq E_i^1$. Let $\chi = \chi_1 \times \cdots \times \chi_r$ where $\chi_i: T(\mathbb{Q}) \setminus T(\mathbb{A}) \rightarrow \mathbb{C}^\times$. The Schwartz function splits as $\varphi_f = \sum_\beta \varphi_f^{\beta,1} \otimes \cdots \otimes \varphi_f^{\beta,r} \in \mathcal{S}(\mathbb{A}_{E_1,f}) \otimes \cdots \otimes \mathcal{S}(\mathbb{A}_{E_r,f})$, as in Proposition 3.1.

Theorem 3.4. *We have*

$$\sum_{n=1}^{\infty} \langle C_\chi, C_n(\varphi) \rangle q^n = \sum_{\beta} \Theta_{\varphi^{\beta,1}}(\tau^\Delta, \chi_1) \cdots \Theta_{\varphi^{\beta,r}}(\tau^\Delta, \chi_r). \quad (3.98)$$

Proof. It follows from combining (3.97) with Proposition 3.1. \square

Remark 3.4. In fact, one can show that that when F is a field, the cycles C_χ and $C_n(\varphi)$ intersect transversely.

4. EXAMPLE OF BIQUADRATIC FIELDS

We consider the setting of a split quadratic space of signature $(2, 2)$. The setting is similar to [Bra23a], but we consider the integral over a product of compact geodesics instead of the the product of a compact geodesic with γ_∞ .

4.0.1. Consider the quadratic space $(V, Q) = (\text{Mat}_2(\mathbb{Q}), 2 \det)$ with the quadratic form

$$2 \det(x) = \text{Tr}(xx^*), \quad (4.1)$$

where the involution is

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix}^* = \begin{pmatrix} d & -b \\ -c & a \end{pmatrix} = S^T \begin{pmatrix} a & b \\ c & d \end{pmatrix}^T S \quad (4.2)$$

with $S = \begin{pmatrix} 0 & 1 \\ -1 & 0 \end{pmatrix}$ and A^T is the transpose of A . In particular, we have $(xy)^* = y^*x^*$. As a bilinear form, the quadratic form is

$$Q(x, y) = \text{Tr}(xy^*) = \text{Tr}(x^*y) \quad (4.3)$$

where Tr is the matrix trace. The spin group $\text{GSpin}_V(\mathbb{Q})$ is isomorphic to

$$\text{GSpin}_V(\mathbb{Q}) \simeq \text{GL}_2(\mathbb{Q}) \times_{\det} \text{GL}_2(\mathbb{Q}) \quad (4.4)$$

and consists of matrices (g_1, g_2) with $\det(g_1) = \det(g_2)$. It acts on $\text{Mat}_2(\mathbb{Q})$ by $\rho(g_1, g_2)y = g_1 y g_2^{-1}$ and preserves the quadratic form \det . The action of $\text{GSpin}_V(\mathbb{Q})$ on V induces a short exact sequence

$$1 \longrightarrow \mathbb{Q}^\times \longrightarrow \text{GSpin}_V(\mathbb{Q}) \xrightarrow{\rho} \text{SO}_V(\mathbb{Q}) \longrightarrow 1 \quad (4.5)$$

where \mathbb{Q}^\times is the center of $\text{GSpin}_V(\mathbb{Q})$. We have

$$\text{SO}_V(\mathbb{Q}) \simeq \text{GSpin}_V(\mathbb{Q}) / \mathbb{Q}^\times. \quad (4.6)$$

The connected component $\mathrm{GSpin}_V(\mathbb{R})^+ = \mathrm{GL}_2(\mathbb{R})^+ \times_{\det} \mathrm{GL}_2(\mathbb{R})^+$ consists of pairs of matrices with (same) positive determinant. It acts transitively on $\mathcal{H} \times \mathcal{H}$ by Möbius transformations in both factors. Let $\tilde{K}_\infty \subset \mathrm{GSpin}_V(\mathbb{R})^+$ be the stabilizer of a point in $\mathcal{H} \times \mathcal{H}$, so that $\mathcal{H} \times \mathcal{H} \simeq \mathrm{GSpin}_V(\mathbb{R})^+ / \tilde{K}_\infty$. The stabilizer of (i, i) is $\mathbb{R}_{>0}(\mathrm{SO}(2) \times \mathrm{SO}(2))$. We can extend the Weil representation from the pair $\mathrm{SO}_V(\mathbb{Q}_v) \times \mathrm{SL}_2(\mathbb{Q}_v)$ to the pair $\mathrm{GSpin}_V(\mathbb{Q}_v) \times \mathrm{SL}_2(\mathbb{Q}_v)$ by

$$\omega(\tilde{g}, h)\varphi(x) = \omega(1, h)\varphi(\rho(\tilde{g})^{-1}x), \quad (4.7)$$

where $\varphi \in \mathcal{S}(\mathrm{Mat}_2(\mathbb{Q}_p))$ is a Schwartz-Bruhat function.

4.1. Locally symmetric space. For the locally symmetric spaces and the special cycles in this setting, we refer to [Bra23a] for more details. Let $M_0(p) \subset \mathrm{Mat}_2(\mathbb{Q})$ be the lattice

$$M_0(p) := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{Mat}_2(\mathbb{Z}) \mid p \mid c, (a, p) = 1, ad - bc > 0 \right\} \quad (4.8)$$

and

$$\widehat{M}_0(p) := \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{Mat}_2(\widehat{\mathbb{Z}}) \mid a_p \in \mathbb{Z}_p^\times, c_p \in p\mathbb{Z}_p \right\}, \quad (4.9)$$

that satisfies $\mathrm{Mat}_2(\mathbb{Q})^+ \cap \widehat{M}_0(p) = M_0(p)$. Let $\varphi_f \in \mathcal{S}(\mathrm{Mat}_2(\widehat{\mathbb{Z}}))$ be the characteristic function of $\widehat{M}_0(p)$. It is preserved by the open compact $\tilde{K}_0(p)$, where $\tilde{K}_0(p) := K_0(p) \times_{\det} K_0(p)$ is an open compact in $\mathrm{GSpin}_V(\widehat{\mathbb{Z}})$ and

$$K_0(p) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} \in \mathrm{GL}_2(\widehat{\mathbb{Z}}) \mid c \in p\widehat{\mathbb{Z}} \right\}. \quad (4.10)$$

We set $\tilde{K} := \tilde{K}_\infty \tilde{K}_0(p)$ and we have

$$Y = \mathrm{GSpin}_V(\mathbb{Q}) \backslash \mathrm{GSpin}_V(\mathbb{A}) / \tilde{K} \simeq Y_0(p) \times Y_0(p)$$

by the strong approximation $\mathrm{GL}_2(\mathbb{A}_f) = \mathrm{GL}_2(\mathbb{Q})^+ K_0(p)$.

4.1.1. For a vector M in $\mathrm{Mat}_2(\mathbb{R})$ with positive determinant, the submanifold \mathcal{D}_M^+ in \mathcal{D}^+ is the image of the map

$$\begin{aligned} \mathcal{H} &\hookrightarrow \mathcal{H} \times \mathcal{H} \\ z &\mapsto (Mz, z). \end{aligned} \quad (4.11)$$

The special cycles C_M is the image of the immersion

$$\Gamma_M \backslash \mathcal{H} \longrightarrow Y_0(p) \times Y_0(p) \quad (4.12)$$

where $\Gamma_M := \Gamma_0(p) \cap M^{-1}\Gamma_0(p)M$. Hence, the special cycles

$$C_n(\varphi) = \sum_{\substack{M \in \Gamma_0(p) \backslash \mathrm{Mat}_2(\mathbb{Q}) / \Gamma_0(p) \\ \det(M)=n}} C_M \quad (4.13)$$

are correspondences in $Y_0(p) \times Y_0(p)$.

4.2. Maximal torus in GSpin_V . Let $L = \mathbb{Q}(\sqrt{D})$ be a real quadratic field of fundamental discriminant D and suppose that p is split in L . Let \mathcal{O}_L be the ring of integers. Let us fix an integer $r \in \mathbb{Z}$ such that $r^2 \equiv D \pmod{4p}$. A form $[a, b, c] = ax^2 + bxy + cy^2$ of squarefree discriminant D is called a Heegner form at p if it satisfies $a \equiv 0 \pmod{p}$ and $b \equiv r \pmod{p}$. Let (u, v) be a positive fundamental solution to the Pell equation $u^2 - Dv^2 = 1$. To every primitive Heegner form $[a, b, c]$ at p of discriminant $D = b^2 - 4ac$ we can associate the matrix

$$\begin{pmatrix} u - bv & -2cv \\ 2av & u + bv \end{pmatrix} \in \Gamma_0(p). \quad (4.14)$$

It is a generator of the (free part of) the orthogonal group of the quadratic form $[a, b, c]$. Its two eigenvalues are $\epsilon_L = u + \sqrt{D}v$ and $\epsilon_L^{-1} = u - \sqrt{D}v$, where ϵ_L is a fundamental unit in \mathcal{O}_L^\times . The eigenvectors are

$$\begin{pmatrix} -b + \sqrt{D} \\ 2a \end{pmatrix}, \quad \begin{pmatrix} -b - \sqrt{D} \\ 2a \end{pmatrix}. \quad (4.15)$$

The embedding $\phi: L \hookrightarrow \text{Mat}_2(\mathbb{Q})$ given by

$$\phi(\sqrt{D}) = \begin{pmatrix} -b & -2c \\ 2a & b \end{pmatrix} \in \Gamma_0(p) \quad (4.16)$$

is optimal in the sense that $\phi(L^\times) \cap \Gamma_0(p) = \mathcal{O}_L^\times$.

4.2.1. Instead of taking a maximal algebraic \mathbb{Q} -torus T in SO_V , let us start with a maximal \mathbb{Q} -torus \tilde{T} in GSpin_V . The image $T(\mathbb{Q}) = \rho(\tilde{T}(\mathbb{Q}))$ in $\text{SO}_V(\mathbb{Q})$ is a maximal \mathbb{Q} -torus and we have an exact sequence

$$1 \longrightarrow \mathbb{Q}^\times \longrightarrow \tilde{T}(\mathbb{Q}) \xrightarrow{\rho} T(\mathbb{Q}) \longrightarrow 1. \quad (4.17)$$

Let L_1 and L_2 be two real quadratic fields with distinct discriminants D_1 and D_2 . Suppose that p is split in both fields. Let $[N_1, r_1, 1]$ and $[N_2, r_2, 1]$ be the two principal² Heegner forms where $N_i := \frac{r_i^2 - D_i}{4}$. Let $\phi_i: L_i \hookrightarrow \text{Mat}_2(\mathbb{Q})$ be the two associated optimal embeddings, given by

$$\phi_i(\sqrt{D}) = \begin{pmatrix} -r_i & -2 \\ 2N_i & r_i \end{pmatrix} \in \Gamma_0(p). \quad (4.18)$$

Combining these two embeddings gives an embedding

$$\phi_1 \times \phi_2: L_1^\times \times_{\mathbb{N}} L_2^\times \hookrightarrow \text{GSpin}_V(\mathbb{Q}) \quad (4.19)$$

and let $\tilde{T}(\mathbb{Q}) \simeq L_1^\times \times_{\mathbb{N}} L_2^\times$ be the image of this embedding. The product $L_1^\times \times_{\mathbb{N}} L_2^\times$ consists of elements (λ_1, λ_2) in $L_1 \times L_2$ with the same nonzero norm. We have $T(\mathbb{Q}) \simeq L_1^\times \times_{\mathbb{N}} L_2^\times / \mathbb{Q}^\times$.

4.2.2. We want to find the étale algebra E associated to \tilde{T} . It is the centralizer of \tilde{T} in $\text{End}(V) = \text{End}(\text{Mat}_2(\mathbb{Q}))$.

Lemma 4.1. *The map*

$$\begin{aligned} \text{Mat}_2(\mathbb{Q}) \otimes_{\mathbb{Q}} \text{Mat}_2(\mathbb{Q}) &\longrightarrow \text{End}_{\mathbb{Q}}(\text{Mat}_2(\mathbb{Q})) \\ a \otimes b &\longmapsto (a \otimes b)x := axb^* \end{aligned} \quad (4.20)$$

is an isomorphism of \mathbb{Q} -algebras, where the involution b^* is as in (4.2).

Proof. The map is a homomorphism of \mathbb{Q} -algebras. Since they both have dimension 16, it is enough to show surjectivity. Let E_{ij} be the standard basis of $\text{Mat}_2(\mathbb{Q})$, that sends the basis vector e_a in \mathbb{Q}^2 to $\delta_{j=a}e_i$. A basis of $\text{End}_{\mathbb{Q}}(\text{Mat}_2(\mathbb{Q}))$ is \mathcal{E}_{ij}^{kl} , given by $\mathcal{E}_{ij}^{kl}(E_{ab}) = \delta_{a=i}\delta_{b=j}E_{kl}$. We have that $E_{kl}E_{ij} = \delta_{l=i}E_{kj}$. Hence, the element $E_{kl} \otimes E_{ij}^*$ acts by

$$(E_{ki} \otimes E_{jl}^*)E_{ab} = E_{ki}E_{ab}E_{jl} = \delta_{a=i}E_{kb}E_{jl} = \delta_{a=i}\delta_{b=j}E_{kl}. \quad (4.21)$$

Hence $E_{kl} \otimes E_{ij}^*$ is sent to \mathcal{E}_{ij}^{kl} , and the map is surjective. \square

We can then map $\text{GSpin}_V(\mathbb{Q})$ in $\text{End}_{\mathbb{Q}}(\text{Mat}_2(\mathbb{Q}))$ by sending (g_1, g_2) to $\det(g_2)g_1 \otimes g_2$. The map is compatible with the actions of $\text{GSpin}_V(\mathbb{Q})$ and $\text{End}_{\mathbb{Q}}(V)$ on V .

Proposition 4.2. *The étale algebra is $E \simeq \mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})$ and the involution is*

$$\epsilon(\sqrt{D_1}, \sqrt{D_2}) = (-\sqrt{D_1}, -\sqrt{D_2}).$$

The fixed subalgebra F is the totally real field $\mathbb{Q}(\sqrt{D_1 D_2})$.

²It represents the unit in the narrow class group.

Proof. Let $\text{End}_{\mathbb{Q}}(\text{Mat}_2(\mathbb{Q}))$ be the endomorphism ring of $\text{Mat}_2(\mathbb{Q})$. Let ϵ_Q be the involution on $\text{Mat}_2(\mathbb{Q}) \otimes \text{Mat}_2(\mathbb{Q})$ defined by

$$Q((a \otimes b)x, y) = Q(x, \epsilon_Q(a \otimes b)y). \quad (4.22)$$

Since $Q(x, y) = \text{Tr}(xy^*) = \text{Tr}(x^*y)$, we have $Q(xb, y) = Q(x, yb^*)$ and $Q(ax, y) = Q(x, a^*y)$. Hence, the involution is given by $\epsilon_Q(a \otimes b) = a^* \otimes b^*$. The image of $\tilde{T}(\mathbb{Q})$ in $\text{End}_{\mathbb{Q}}(\text{Mat}_2(\mathbb{Q})) \simeq \text{Mat}_2(\mathbb{Q}) \otimes_{\mathbb{Q}} \text{Mat}_2(\mathbb{Q})$ is

$$J = \{N(x_2)x_1 \otimes x_2 \in \text{Mat}_2(\mathbb{Q}) \otimes_{\mathbb{Q}} \text{Mat}_2(\mathbb{Q}) \mid (x_1, x_2) \in L_1^{\times} \times_N L_2^{\times}\}. \quad (4.23)$$

The étale algebra of endomorphisms commuting with J is $E = L_1 \otimes L_2$. Note that when restricted to L_i the involution x^* acts like the Galois involution $x \mapsto x'$, i.e. we have $\phi(x') = \phi(x)^*$. Hence, the involution ϵ_Q restricted to E is $\epsilon_Q(x_1 \otimes x_2) = x'_1 \otimes x'_2$ where x'_i is the Galois conjugate of x_i . It follows that the étale algebra is $E \simeq \mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})$ with the involution sending $\sqrt{D_i}$ to $-\sqrt{D_i}$. \square

4.2.3. The identity matrix $x_0 = \mathbf{1}_2$ is an $L_1 \otimes L_2$ module generator of $\text{Mat}_2(\mathbb{Q})$. Hence, we have an isomorphism of vector spaces,

$$\begin{aligned} E &= L_1 \otimes L_2 \longrightarrow \text{Mat}_2(\mathbb{Q}) \\ \lambda_1 \otimes \lambda_2 &\longmapsto \phi_1(\lambda_1)\phi_2(\lambda_2)^*. \end{aligned} \quad (4.24)$$

Thus, there exists an $\alpha \in F^{\times}$ such that $(E, Q_{\alpha}) \simeq (\text{Mat}_2(\mathbb{Q}), \det)$. At the level of the torus, we have

$$\mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})^1 \simeq T(\mathbb{Q}) \simeq \rho(L_1^{\times} \times_N L_2^{\times}). \quad (4.25)$$

4.2.4. Over \mathbb{R} the embedding (4.19) becomes

$$\phi_1 \times \phi_2: (L_1 \otimes \mathbb{R})^{\times} \times_N (L_2 \otimes \mathbb{R})^{\times} \hookrightarrow \text{GSpin}_V(\mathbb{R}). \quad (4.26)$$

The embeddings can be diagonalized over \mathbb{R} as $\phi_i(\lambda) = B_i \begin{pmatrix} \lambda_{\sigma} & 0 \\ 0 & \lambda'_{\sigma} \end{pmatrix} B_i^{-1}$ where $\lambda_{\sigma} = \sigma(\lambda) \in \mathbb{R}$ for an embedding σ , where λ' is the Galois conjugate of λ and

$$B_i = \begin{pmatrix} -r_i + \sqrt{D_i} & -r_i - \sqrt{D_i} \\ 2N_i & 2N_i \end{pmatrix} \in \text{GL}_2(\mathbb{R})^+. \quad (4.27)$$

(If $N_i < 0$ then we exchange the two columns to have positive determinant.) Let us fix the point $(z_1, z_2) := (B_1 i, B_2 i)$. Its stabilizer in $\text{GSpin}_V(\mathbb{R})^+$ is $\tilde{K}_{\infty}(z_1, z_2) = (B_1, B_2)\mathbb{R}_{>0}(\text{SO}(2) \times \text{SO}(2))(B_1^{-1}, B_2^{-1})$. Over \mathbb{R} , the torus can be diagonalized as

$$\tilde{T}(\mathbb{R}) = (B_1, B_2)\tilde{T}_0(\mathbb{R})(B_1^{-1}, B_2^{-1}) \quad (4.28)$$

where $\tilde{T}_0(\mathbb{R}) \simeq (\mathbb{R}^{\times})^2 \times_N (\mathbb{R}^{\times})^2$ are pairs of diagonal matrices with same determinant. The preimage $\tilde{K}_{T, \infty} = (\phi_1 \times \phi_2)^{-1}(\tilde{K}_{\infty})$ of \tilde{K}_{∞} by $\phi_1 \times \phi_2$ (tensoring with \mathbb{R}) is $\mathbb{R}_{>0}(\pm 1, \pm 1)$. Hence

$$\mathcal{D}_T^+ \simeq \tilde{T}(\mathbb{R})^+ / \tilde{K}_{T, \infty} \simeq \mathbb{R}_{>0}^2. \quad (4.29)$$

At the level of the locally symmetric spaces, the embedding is

$$\begin{aligned} (\phi_1 \times \phi_2): (\epsilon_{L_1}^{\mathbb{Z}} \times \epsilon_{L_2}^{\mathbb{Z}}) \backslash \mathbb{R}_{>0}^2 &\longrightarrow Y_0(p) \times Y_0(p) \\ (\epsilon_{L_1}^{\mathbb{Z}} \times \epsilon_{L_2}^{\mathbb{Z}})(t_1, t_2) &\longmapsto (\Gamma_0(p) \times \Gamma_0(p))(B_1, B_2)(t_1 i, t_2 i). \end{aligned} \quad (4.30)$$

As t_1 and t_2 range over \mathbb{R} , the image of $(t_1 i, t_2 i)$ is $\gamma_{\infty} \times \gamma_{\infty}$ and we get the following.

Proposition 4.3. *The image of (4.30) is $\gamma_{\theta_1} \times \gamma_{\theta_2}$, where γ_{θ_i} be the geodesic joining $\frac{-r_i - \sqrt{D_i}}{2N_i}$ to $\frac{-r_i + \sqrt{D_i}}{2N_i}$.*

As in [Bra23a], we use that $\langle C_T, C_n(\varphi) \rangle = \langle \gamma_{\mathcal{O}_1}, T_n \gamma_{\mathcal{O}_2} \rangle$ to deduce that

$$\sum_{n=1}^{\infty} \langle \gamma_{\mathcal{O}_1}, T_n \gamma_{\mathcal{O}_2} \rangle q^n \quad (4.31)$$

is a diagonal restriction of a Hilbert modular form for a subgroup of $\mathrm{SL}_2(\mathbb{Q}(\sqrt{D_1 D_2}))$.

- Remark 4.1.* 1. The space $(\epsilon_{L_1}^{\mathbb{Z}} \times \epsilon_{L_2}^{\mathbb{Z}}) \backslash \mathbb{R}_{>0}^2$ on the left handside of (4.30) is just one of the connected components of the adelic space Y_T . The geodesic $\gamma_{\mathcal{O}_i}$ is the geodesic attached to the identity in the narrow class group $\mathcal{C}_{D_i}^+$. In general, the cycle C_{χ} should be a linear combinations of product of geodesics $\gamma_I \times \gamma_I'$ attached to a class in the class group of the torus $E^1 = \mathbb{Q}(\sqrt{D_1}, \sqrt{D_2})^1$, and weighted by χ . However, this class group is not the product of the narrow class groups $\mathcal{C}_{D_i}^+$.
2. One could also consider the case where E is a quartic field that is not a biquadratic field. For example if E has two real and one complex place, then the quadratic space is of signature $(3, 1)$ and the space Y is a Bianchi modular surface attached to a quadratic field K . The image of E_{∞}^1 is a geodesic that should come from a quadratic extension of K . It would be interesting to compute explicitly this extension, associated to the initial extension E/F .
3. A similar generating series of intersection numbers on a compact Shimura curve have been considered by Rickards [Ric22]. It should also follow from the seesaw argument that it is the diagonal restriction of a Hilbert modular form.

5. SPANS OF DIAGONAL RESTRICTIONS AND TORIC CYCLES

Let (V, Q) be a rational quadratic space of even dimension and signature (p, q) with $p \geq q > 0$. Let $\varphi = \mathbf{1}_{\widehat{L}}$ be the characteristic function of a lattice $\widehat{L} \subset V_{\mathbb{A}_f}$, such that $L = \widehat{L} \cap V$ is even and unimodular. By Poincaré duality, the pairing

$$\langle -, - \rangle_Y : H_q(Y, \mathbb{C}) \times H^q(Y, \mathbb{C}) \longrightarrow \mathbb{C} \quad (5.1)$$

is non-degenerate. For a subspace $U \subset H^q(Y, \mathbb{C})$ let $U^{\perp} \subset H_q(Y, \mathbb{C})$ denote the orthogonal complement with respect to the pairing. If we suppose that q is odd, then the Kudla-Millson lift is in fact a lift

$$\Theta = \Theta_{\varphi}^V : H_q(Y, \mathbb{C}) \longrightarrow S_d(\mathrm{SL}_2(\mathbb{Z})) \quad (5.2)$$

into the space of cusp forms of weight $d = \frac{p+q}{2}$; see [KM90, Theorem. 2]. On the other hand, the Kudla-Millson lift has an adjoint

$$\overline{\Theta} : S_d(\mathrm{SL}_2(\mathbb{Z})) \longrightarrow H^q(Y, \mathbb{C}) \quad (5.3)$$

defined by

$$\overline{\Theta}(f) = \int_{\mathrm{SL}_2(\mathbb{Z}) \backslash \mathcal{H}} \overline{\Theta_{\varphi}(\tau)} f(\tau) \frac{dx dy}{y^{2-d}}. \quad (5.4)$$

It satisfies

$$\langle \Theta(C), f \rangle_{\mathrm{pet}} = \langle C, \overline{\Theta}(f) \rangle_Y \quad (5.5)$$

where the pairing on the left

$$\langle -, - \rangle_{\mathrm{pet}} : S_d(\mathrm{SL}_2(\mathbb{Z})) \times S_d(\mathrm{SL}_2(\mathbb{Z})) \longrightarrow \mathbb{C} \quad (5.6)$$

is the Peterson inner product.

Proposition 5.1. *Let V be a quadratic space of dimension $p + q > 4$, where $p \geq q > 0$ and q is odd. Then the lift $\overline{\Theta}$ is injective and the lift Θ is surjective.*

Proof. We have $p + q > 4 = \max(4, 3 + r)$ where r is the Witt index. Moreover, we assumed that L is an even unimodular lattice. Hence, the injectivity of $\bar{\Theta}$ is the content of Corollary 1.2 of [BF10]. Suppose that $f \in S_d(\mathrm{SL}_2(\mathbb{Z}))$ is a nonzero cusp form that is not contained in the image of Θ . Without loss of generality we can assume that f is orthogonal to $\mathrm{Im}(\Theta)$ with respect to the Peterson inner product, otherwise we replace f by $f - \mathrm{proj}(f)$ where $\mathrm{proj}(f)$ is the orthogonal projection of f onto $\mathrm{Im}(\Theta)$ with respect to the Peterson inner product. Hence, for every $C \in H_q(Y, \mathbb{C})$ we have

$$0 = \langle \Theta(C), f \rangle_{\mathrm{pet}} = \langle C, \bar{\Theta}(f) \rangle_Y. \quad (5.7)$$

Since the pairing is non-degenerate, this implies that $\bar{\Theta}(f) = 0$. By the injectivity of $\bar{\Theta}$ it follows that $f = 0$, and that Θ is surjective. Note that we have $\mathrm{Im}(\Theta) = \ker(\bar{\Theta})^\perp$ and $\ker(\Theta) = \mathrm{Im}(\bar{\Theta})^\perp$. \square

Let S be the set of characters $\chi: \mathrm{T}(\mathbb{Q}) \backslash \mathrm{T}(\mathbb{A}) \rightarrow \mathbb{C}^\times$ with the same assumptions as in the rest of the paper. We define two following two subspaces. First let

$$H_T := \mathrm{span} \{ C_\chi \mid \chi \in S \} \subset H_q(Y, \mathbb{C}) \quad (5.8)$$

be the homology spanned by the cycles C_χ for $\chi \in S$. For every cycle C_χ , the lift $\Theta(C_\chi)$ is the diagonal restriction of a product of Hilbert modular forms for $\mathrm{SL}_2(F)$. Let

$$S_T := \mathrm{span} \{ \Theta(C_\chi) \mid \chi \in S \} \subset S_d(\mathrm{SL}_2(\mathbb{Z})) \quad (5.9)$$

its span. Let $H_{\mathrm{cycle}} \subset H_{pq-q}(Y, \partial Y, \mathbb{C})$ be the homology spanned by the special cycles $C_n(\varphi)$. Let $H_{\mathrm{cycle}}^\perp \subset H_q(Y, \mathbb{C})$ be the span of the cycles C that satisfy $\langle C, C_n(\varphi) \rangle = 0$ for every $C_n(\varphi)$.

Corollary 5.1.1. *Let V be a quadratic space of dimension $p + q > 4$, where $p \geq q > 0$ and q is odd. We have the following equality*

$$\dim(S_d(\mathrm{SL}_2(\mathbb{Z}))) - \dim(S_T) = \dim(H_q(Y, \mathbb{C})) - \dim(\mathrm{span}\{H_{\mathrm{cycle}}^\perp, H_T\}). \quad (5.10)$$

Proof. Since Θ is surjective we have an isomorphism

$$\Theta: H_q(Y, \mathbb{C}) / \ker(\Theta) \rightarrow S_d(\mathrm{SL}_2(\mathbb{Z})). \quad (5.11)$$

Since S_T is the image of H_T , the isomorphism restricts to an isomorphism

$$\Theta: H_T / \ker(\Theta) \cap H_T \rightarrow S_T. \quad (5.12)$$

We deduce from (5.11) that

$$\dim(S_d(\mathrm{SL}_2(\mathbb{Z}))) = \dim(H_q(Y, \mathbb{C})) - \dim(\ker(\Theta)) \quad (5.13)$$

and from (5.12) that

$$\begin{aligned} \dim(S_T) &= \dim(H_T) - \dim(\ker(\Theta) \cap H_T) \\ &= \dim(\mathrm{span}\{\ker(\Theta), H_T\}) - \dim(\ker(\Theta)). \end{aligned} \quad (5.14)$$

The result follows by taking the difference of (5.14) and (5.13) and using that $\ker(\Theta) = \mathrm{Im}(\bar{\Theta})^\perp = H_{\mathrm{cycle}}^\perp$. The last equality is due to Kudla and Millson [KM88, Theorem. 4.2]. We recall the proof. First, if $C \in H_{\mathrm{cycle}}^\perp$, then $C \in \ker(\Theta)$ since the Fourier coefficients of $\Theta(C)$ are $\langle C, C_n(\varphi) \rangle = 0$. Hence, we have $H_{\mathrm{cycle}}^\perp \subset \ker(\Theta)$. On the other hand, consider the n -th Poincaré series of weight d defined

$$P_n(\tau) = c \sum_{\gamma \in \Gamma/\Gamma_\infty} \frac{e^{2i\pi n\gamma\tau}}{j(\gamma, \tau)^d}. \quad (5.15)$$

The series converges when $p + q > 4$ and is a cusp form. The constant c is chosen such that $\langle f, P_n \rangle_{\mathrm{pet}} = a_n(f)$ is the n -th Fourier coefficients of f . Now suppose that C is in $\mathrm{Im}(\bar{\Theta})^\perp$. In particular, for every $n > 0$ we have

$$0 = \langle C, \bar{\Theta}(P_n) \rangle = \langle \Theta(C), P_n \rangle_{\mathrm{pet}} = \langle C, C_n(\varphi) \rangle. \quad (5.16)$$

Hence, we have $\mathrm{Im}(\bar{\Theta})^\perp \subset H_{\mathrm{cycle}}^\perp$ and the equality $\ker(\Theta) = \mathrm{Im}(\bar{\Theta})^\perp = H_{\mathrm{cycle}}^\perp$ follows from $\ker(\Theta) = \mathrm{Im}(\bar{\Theta})^\perp$. \square
